Although Mayor James Couzens of Detroit was selected as a member of the conference primarily for geographical reasons, it appears that much is expected of him as a spokesman for the automotive industry. Because of the fact that he represents the great automobile manufacturing center, it is reasonable to believe that his advice will be taken on matters relating to the trade. Many automobile manufacturers conferred with the Mayor before he came here. He is a member of the Committee on Unemployment Statistics and the Committee on Emergency State and Municipal Measures and Public Works. In the formal call for the conference the Department of Commerce erroneously listed Couzens as vice-president of the Ford Motor Co.

## CREDITORS EXTEND TIME

PHILADELPHIA, Sept. 28—A majority of the creditors of the Storage Battery & Appliance Co. of Ohio agreed at a meeting here to grant the company an extension of 12 months and a committee was appointed to make recommendations for future action. Operations at the factory will be continued.

## PLAN PETROLEUM MEETING

NEW YORK, Sept. 28—The directors of the American Petroleum Institute have tentatively decided to hold the second annual meeting at Kansas City, Nov. 15, 16 and 17, provided satisfactory arrangements can be made to insure adequate accommodations for members. The annual meeting last year was held in Washington.

General Motors' vote of confidence in Detroit as automotive center of world

## Offices of G. M. C. Largest of Kind

### Mammoth Detroit Structure Will Likewise House Representa- tives of Parts Makers

DETROIT, Sept. 26—Plans for centralization of control of the many interests of General Motors have been brought to perfection at a time almost coincident with the final construction details of its immense general office building, declared to be the largest office building of its kind in the world and the peer of all buildings devoted to the needs of any one industry.

All but two of its fifteen stories will be occupied by the executive and general offices of the corporation. Executive committee and operating committee meetings will be held in these offices at monthly and semi-monthly intervals. Special directors' offices will closet director meetings on such occasions as these are held in Detroit. The main floor will display the automobiles, trucks and tractors made by the companies comprising the corporation.

The second and third floors will be leased to representatives of manufac-

turers making parts and accessories for the industry, thus making the building, in a larger sense, the automotive center of the world rather than exclusively General Motors headquarters.

A large auditorium in the rear will be used for the larger functions of the corporation, and will also be available to the industry as a whole and to the city of Detroit, as an exposition hall.

The building occupies two entire city blocks, practically at the intersection of the two main thoroughfares, Grand Boulevard and Woodward Avenue. It is in the geographical center of the city at a point where eventually, it is thought, will be the greatest business center.

### BULLETIN FOR N. A. C. C. MEMBERS

NEW YORK, Sept. 27—The National Automobile Chamber of Commerce has begun sending to its members a weekly bulletin summarizing briefly conditions in the basic industries together with information covering employment, building, foreign trade, banking and commodity prices. It includes a survey of retail trade as compiled by Bradstreet and a chart showing the factors in motor car use compared with bank clearings and the production of pig iron. The first of these bulletins is based upon the statement that "basic industries are gradually gaining momentum."

## Plan Removes Most of Moline Plow Debt

### Old Securities Will Be Exchanged for New Leaving Indebted- ness Less Than \$3,000,000

CHICAGO, Sept. 26—The new reorganization plan for the Moline Plow Co. was made public here yesterday by Frank O. Wetmore, president of the First National Bank and chairman of the bankers' and creditors' committee of the company. The plan provides that all debts of the company, amounting to slightly less than \$25,000,000 with interest be discharged with 50 per cent of bonds, 50 per cent of first preferred stock and a bonus of common in a new company.

Until the majority of the creditors act favorably upon the plan it cannot become operative. There may be some slight changes in detail.

Without assessment the old securities will be exchanged for new, of which there will be authorized \$12,500,000 first preferred, \$7,500,000 second and 200,000 shares of no par value common.

If this plan works out the company will be left with debts of not more than \$3,000,000. It will have a large working capital.

## METAL MARKETS

**U**NDoubtedly orders aggregating a respectable tonnage were placed on the order books of sheet mills previous to the withdrawal of the concessions recently in vogue. Consumers had been posted as to what was contemplated and many covered themselves well in advance at the formerly current price levels. With sheets to the front as the leading steel commodity in point of market activity, producers of those descriptions of finished steel which are still conspicuously in the doldrums are asking themselves whether it might not be advisable to emulate the example of the sheet makers. This would imply a cutting of prices, and then, once the momentum of revived demand begins to show, the issuing of notice that the concessions would be abrogated in a few days so as to afford buyers an opportunity to place orders while prices are still an inducement. There is no doubt that in the case of quite a few sheet mills the prices at which they booked orders a few weeks ago represented cost or even below cost. These same prices, however, in an operation of 60 per cent of plant capacity may yield a small margin of profit where they resulted in positive loss when operations were on a 20 per cent of capacity basis. With a view to raising their rate of operations producers of finished steel other than sheets are considering the advisability of temporary price cuts. In fact, next to the further price reductions that would be made possible by an early scaling down of freight rates, no other factor looms so big as an incentive to downward revision as the eagerness of all producers to bring a greater part of their capacity into active operation. It is generally conceded by the steel industry that the war has left it over-equipped. Until a revival in export demand absorbs a greater tonnage of steel, there is bound to be in evidence in the domestic market a certain amount of potential selling pressure resulting from the surplus of mechanical equipment over that which the domestic demand calls for. By this it is not meant to imply that there are any large tonnages of steel pressing on the market at this time. The surplus equipment referred to is, in fact, idle. Nor are these observations to be construed as in any way running counter to the opinion which is held in many quarters and for which there is ample justification that, taking into consideration prevailing prices for labor, freight and other items that enter into steel making, the market is far more in buyers' favor than in that of producers.

**Pig Iron.**—Automotive foundries are inquiring for somewhat larger tonnages. Sellers appear unwilling to accept commitments for first quarter 1922. The market generally may be characterized as firm.

**Steel.**—Somewhat more interest is being shown by automotive consumers in alloy steels, which have been almost dormant for a long while. The old 2.50c. quotation in the cold-finished steel market has disappeared, and producers seem eager for orders at \$2 to \$3 below this level. Automotive consumers continue to be the best customers which the strip-steel market has. Fair-sized lots of cold-rolled are inquired for, to be shipped in October. The asking price for the cold-rolled is 3.75c. and for the hot-rolled 2.15c., but these prices are being shaded down to 3.50c. and 2.15c. respectively. Automobile sheets are in good demand at 4.35c. for No. 22 gage.

**Aluminum.**—Prices on imported ingot metal are being slashed merrily and offers

at as low as 17c. for 98 to 99 per cent pure have been reported, although there is doubt whether deliveries would be made at this level. German aluminum sheets are offered at 30@32c. for flats and coils.

**Copper.**—Brass interests are buying more liberally. The market, however, continues only barely steady.

**Tin.**—The market has turned firmer but, as far as concerns buying by consumers, dull.

**Lead.**—Supplies of spot lead available in the East are light and the demand from consumers other than battery makers is keeping up well.

**Zinc.**—As the result of better inquiry from galvanizers, the market's general tone has improved. Production is still being curtailed and, as a result, steadiness prevails.

## FINANCIAL NOTES

**Goodyear Tire & Rubber Co.** 8 per cent twenty-year sinking fund bonds to the amount of \$750,000 will be retired Nov. 1, as provided for in the indenture. The total issue is \$30,000,000.

**Wilton Tool Co., Detroit,** is issuing \$250,000 in 8 per cent cumulative preferred stock to provide capital for expansion. Wilton Tool Co. combines the businesses of the Wilton Tool & Mfg. Co., the Twentieth Century Heat Treating Co. and the Wilton Engineering Co.

**McGraw Tire & Rubber Co.** shows net earnings for August of \$109,000, against \$33,000 for July, \$20,000 for June and deficits of \$10,000 in May and \$40,000 in April.

**Chalmers Motor Corp.** 6 per cent notes due Oct. 1, 1922, totaling \$33,684.80, have been sold at public auction at 50 cents on the dollar, or \$16,842.40.

**General Motors Corp.** directors at a meeting in New York declared a dividend of 25 cents a share on the common stock, \$1.50 on the 6 per cent preferred, \$1.50 on the 6 per cent debentures and \$1.75 on the 7 per cent debentures, payable Nov. 1.

**Kelsey Wheel Co.** has declared the regular quarterly dividend of 1½% on the preferred stock, payable Nov. 1 to stock of record Oct. 20.

**Reynolds Spring Co., Jackson, Mich.,** has declared a dividend of 1½ per cent on its preferred Class A stock, payable, Sept. 30.

Kess-Line to Occupy  
Liberty Car Plant Oct. 1

**DETROIT, Sept. 26**—Kess-Line Motors, an offspring of the Kessler Motor Co., will take possession of the former Liberty Motor Car Co. plant here on Oct. 1, and will prepare for the production of the Kess-Line eight, which will be introduced at the national automobile shows in January.

The factory will afford 70,000 ft. of manufacturing space and will have a production capacity of 60 cars a day. It is located on the Detroit Terminal line, and is well planned for automobile manufacture. Officers of the company are M. C. Kessler, president; W. H. Radford, vice-president, and H. H. Scott, secretary and treasurer. Kessler is president of Kessler motors, Radford an executive prominent in car manufacture since 1903, and Scott a former executive of the Fisher Body Co.

Program Outlined  
to Promote SalesEastern Automotive Equipment  
Men Meet to Discuss Pro-  
motion

**NEW YORK, Sept. 26**—A sales promotion program to supplement that of the Automotive Equipment Association was authorized here by the Eastern Automotive Equipment Association. Members along the Atlantic seaboard States from Maine to Maryland were represented at a meeting and reviewed the plan of a 4-page merchandising letter which will be sent out in the name of the association to a list of dealers and garagemen in the territory covered by the members.

The letter, which is illustrated, tells of the opportunity for profit in the sale of automotive equipment, tells how to sell it and shows helps in the way of display boards and advertising material which dealers can obtain from the manufacturers through the jobbers.

The association voted to hold its annual meeting in New York on Tuesday of show week, when the following nominations for officers and directors will be voted upon: President, H. M. Savage, Whetmore-Savage Co., Boston; vice-president, G. N. Shafer, W. E. Pruden Hardware Co., New York City; secretary, T. B. O'Neill, Martin-Evans Co., Brooklyn; treasurer, Bernard Miller, Economy Auto Supply Co., Newark; directors, F. J. Murray, Post & Lester, Boston; George B. Shearer, Gaul, Derr & Shearer Co., Philadelphia; E. T. Ball, Joseph Straus & Co., Buffalo; R. J. Cahall, Cahall Motor Supply Co., Philadelphia; Wallace D. Page, American Motor Equipment Co., Boston; E. T. Satchel, Motor Accessories Co., Allentown, Pa.; J. R. Hunt, of the J. R. Hunt Automotive Supply Co., Baltimore.

## JACKMAN MOTORS AUCTIONED

**JOLIET, ILL., Sept. 26**—The stock and fixtures of the Jackman Motor Co. of this city have been sold at public auction, following the recent action of the courts in declaring the concern bankrupt. A schedule of the company's assets indicated approximately \$100,000, while the liabilities total \$130,000. The creditors include the Joliet National Bank, Will County National Bank, the Industrial Acceptance Corp. of Chicago, and a number of local firms. It is expected that the business will be concluded in the near future and that the claims will be satisfied, probably at 50 cents on the dollar, governed largely by the court costs.

## SAYERS SIX LOWER

**CINCINNATI, Sept. 27**—Sayers & Scoville Co. has reduced prices on its roadster and five passenger touring car from \$1,945 to \$1,795.

## MEN OF THE INDUSTRY

A. J. Banta has taken charge of the plant of the Clydesdale Motor Truck Co. as vice-president and general manager. He formerly was connected with the Locomobile, Maxwell and Premier companies.

Charles S. Turner has been appointed to the sales organization of Liberty Motor Car Co. For the past five years he has been connected with Robertson-Cole Co., New York, in foreign sales development.

Frank E. Knickerbocker, formerly in charge of the Flint branch of Samson Tractor Co., is in charge of a new factory branch of Oldsmobile in Lansing, Mich. From this branch also J. W. Rapley will handle general distribution in Michigan.

F. A. Petrie, assistant sales manager of Dort Motor Car Co., Flint, has resigned to become vice-president of the Mission Motor Co., Los Angeles, southern California distributors of Dort. He will handle the wholesale end of the business.

Bert Hunt of William Hunt & Co., Johannesburg, South Africa, is on the way to the United States to confer with manufacturers whom he represents. William Hunt & Co. distributes the Chevrolet and the Indian motorcycle in South Africa.

Hugo C. Gibson, formerly chief engineer for the R. & V. Motor Co., is at present active in placing upon the market a number of novel improvements in the automotive field ranging from the chassis to the lighting system. This he is doing in addition to his automotive consulting work.

W. B. Clowes, assistant sales manager for a number of years with the Elsemann Magneto Corp., has severed his connection with that company. He has not stated his future plans. O. S. Stanley, formerly assistant service manager in New York City of the American Bosch Magneto Corp. succeeds Clowes.

Jay Dewey has been appointed Pacific coast sales manager of the George W. Davis Motor Car Co., with headquarters at Los Angeles. Dewey has been identified with the automotive industry for many years and resigns the position of general sales manager for the Lexington Motor Co. to accept the new appointment.

R. A. Wilson, production manager of the Leach Motor Car Co. of Los Angeles, Cal., is in eastern manufacturing centers on an extensive buying trip. Raw materials are being purchased as well as a large amount of machinery for the motor plant. Mr. Wilson plans to visit automobile manufacturing centers at Detroit, Indianapolis, Rochester and Buffalo before returning, about Nov. 1.

Walter E. Myers, president of the Denman-Myers Cord Tire Co. of Cleveland, will arrive in New York on the Empress of India on Sept. 29. Myers has been in Europe since Aug. 13, when he went to attend the Ecumenical Conference in London. For some weeks prior to the conference and since the conference Myers visited various parts of Europe to make a study of business conditions, particularly as they related to the rubber industry.

Forrest P. Richardson, purchasing agent of the Leach Biltwell Motor Car Co. of Los Angeles, has been appointed assistant general manager of that company. Richardson, who also is a director of the Leach Co., has been connected with the concern for more than two years and with Leach was one of the founders of the enterprise, which now is

a \$5,000,000 corporation and equipped to produce approximately 1200 cars a year. The company is in full production, having several months orders ahead.

R. A. Picard, for several years sales manager of A. J. Picard & Co., automotive equipment jobber in New York, has resigned to become sales manager of the Metal Stamping Co., Long Island City. Picard has been active in association work in the jobber field, having been secretary of the standardization committee of the Automotive Equipment Association and secretary of the Eastern Automotive Equipment Association. He served in the World War as an officer in the Motor Transport Corps.

W. T. Bush has been named director of sales for Gray-Dort Motors, Ltd., Chatham, Ont., to succeed W. G. Bell, who has taken up other work in the organization. Bush was at one time general sales manager in Canada of the Studebaker Corp. of Walkerville. Later he was transferred to the head office at South Bend as assistant general sales manager, still retaining his connection in the Canadian organization. Prior to his appointment with the Gray-Dort company he held an important executive position with the Packard Motor Car Co. of Detroit.

J. H. McDuffee, long identified with the motor car industry, will become assistant general manager of the Cole Motor Co., Indianapolis, Oct. 1. McDuffee has been with the industry almost since its first beginnings, his first connection being with the Locomobile in New York. Later he was associated with the Willys-Overland Corp. as assistant general sales manager, and president of the Chicago Subsidiary Corp. Three years ago he went to Indianapolis with Carl G. Fisher, owner of the Indianapolis Motor Speedway, and since then has been connected with Fisher.

George Shortmeyer, formerly New York manager for the Madison Rubber Co. and later district manager at New York for the Sinclair Oil Co., has succeeded O. S. Stanley as manager of the branch of the American Bosch Magneto Corp. in that city. Charles L. Shedd has been appointed manager of the Detroit branch in the place of Roy Davey, who has been made manager of the manufacturing sales department at Springfield, Mass. Shedd at one time was promotion manager of the truck division of the Packard Motor Car Co. at Detroit and subsequently served as distributor for that company at Omaha. Recently he acted as sales manager of the Republic Truck Corp. at New York.

## JACKSON LOWERS PRICES

JACKSON, MICH., Sept. 26 — The Jackson Motors Corp. has made the following reductions:

	Old	New
4 passenger touring.....	\$2,685	\$2,285
5 passenger touring.....	1,950	1,635
Coupe .....	3,750	2,985
Sedan .....	3,750	2,985

## NEW PRICES FOR ATTERBURY

BUFFALO, Sept. 26—The Atterbury Motor Car Co. of Buffalo announces new prices on its various truck models, effective Oct. 1. The prices are f.o.b. Buffalo and do not include the United States war tax. The prices are:

	New Price	Old Price
1½ ton.....	\$2,475	\$2,775
2½ ton.....	3,175	3,375
3½ ton.....	3,975	4,175
5 ton.....	4,975	5,575

Used Car Methods  
Menace to IndustryAllowances Threatening Not Only  
to Dealer but Also to Manufacturer, Reeves Says

NEW YORK, Sept. 28—The real menace to the automotive industry is the unscientific way in which used cars are handled, is the opinion of Alfred Reeves, general manager of the National Automobile Chamber of Commerce. In an address before the Automobile Dealers Association of New York he declared that "it threatens not only the prosperity of the dealer but through him the stability and standing of the manufacturer."

"It is not alone the dealer's problem and efforts to better it should be made by the manufacturers in co-operation with their distributors," Reeves declared.

## Lower Insurance Urged

Among other questions which should be given careful consideration, according to Reeves, are lower insurance rates; better, although not necessarily cheaper service; fewer taxes; a decrease in accidents and a campaign which has been started by some interests to have motorists pay for the building of good roads, although the highways benefit the public as a whole. Reverting to the used car problem, he said:

"During the stress of the competition of the past six months, the ridiculous allowances for second-hand cars were a form of price cutting. However, it was the same when there was an over-demand for cars. Even in those days, dealers allowed more than cars were worth, so that car selling became largely a matter of trading with the owner of an old car.

"The used car situation may not be better until human nature is better. Everyone has his own right to judge car values and it will take a lot of educating to prove to dealers the real value of used motor cars and trucks.

## Allowances Too High

"The used car problem should be studied by the best brains of manufacturers and their dealers. Unfair allowances and inefficient selling plans, with the resultant money loss, are a blot on the escutcheon of one of America's greatest industries.

"Some car manufacturers have not been blameless in this for under the stress of recent conditions they have sometimes pressed the dealer to take new cars in greater quantities than he has been able to handle. They have also overtraded through their branches.

"I look to see the car and truck manufacturers, by advertising and sales promotion work, help to move their own makes that their dealers have on hand, and thus broaden the market for new cars. Sales managers must appreciate the need to help dealers in the greatest of all obstructions to increased new car sales."

## REDUCTION FOR TULSA

TULSA, OKLA., Sept. 26—The Witt-Thompson Motor Co. has reduced prices on the Tulsa roadster and five-passenger touring car, Model E 1-3, from \$1,285 to \$1,175.

# Calendar

## SHOWS

Sept. 28 - Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 14-19—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association, Fourth Regiment Armory.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Grand Central Palace, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Jan. 30-Feb. 4—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.

Feb. 6 to 11—Winnipeg, Can.,

Automotive Equipment Show, Western Canadian Automotive Association.

Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

September—Buenos Aires, Argentina, Passenger Cars and Equipment, La Pabellon de las Rosas, Automovil Club Argentino.

September—Buenos Aires, Argentina, Cars, Trucks, Tractors, Farm Lighting Plants and Power Farming Machinery, Palermo Park; Sociedad Rural Argentina.

September—Luxemburg, Luxemburg, Agricultural Sample Exhibition.

Sept. 23-Oct. 2—Berlin, German National Automobile Show, Auspices of German Automobile Mfg. Ass'n and German Automobile Club.

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais,

Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Oct. 10-22—Olympia, England, Truck Show, Nov. 4-12—Car Show, Nov. 28-Dec. 3—Motorcycle Show.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

November 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.

Nov. 26-Dec. 3—Shanghai, China, Automobile Show.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador, Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibit in connection with the Brazilian Centenary As-

sociação Automobilista Brasileira.

## CONVENTIONS

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Nov. 15-17—Kansas City, Second Annual Meeting of American Petroleum Institute.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

Jan. 17-20, 1922—Chicago, American Road Builders Association.

S. A. E. MEETINGS

Detroit, Sept. 23, Oct. 21, Nov. 18, Dec. 23, Feb. 24, March 24, April 28, May 26.

Dayton, Oct. 1—First Fall Meeting.

New York, Jan. 10-13, 1922—Annual Meeting.

## Underwriters Plan to Reduce Policies

### Propose to Cut Automobile Risks in Two—Recognition Given Moral Hazard

NEW YORK, Sept. 28—A general reduction in the size of automobile insurance policies, in most cases amounting to 50 per cent, was announced at the annual conference of the National Automobile Underwriters, held at the Commodore Hotel here. It was explained that while policies issued last year would be continued, underwriters throughout the country were more cautious in renewing or issuing policies.

Several speakers spoke of policies issued a year ago as a "potential moral hazard," declaring that an unscrupulous automobile owner can risk the loss of his car under last year's policy knowing that he can recover more than the present sale price for it on his policy.

It was the consensus among those present that last year was unusual in the automobile insurance business because of the violent changes which took place and the resulting experiences of the companies, but the belief was expressed that the worst had been passed and that with new restrictions imposed on automobile owners by legislation in many states there would be a continued improvement.

Some of those who addressed the gathering declared that the business could be stabilized through compelling policy holders to take greater interest in their cars, and a lengthy discussion ensued on a means to bring this about.

It was pointed out that owners were negligent in the care of appurtenances on their cars, and that not infrequently when filing claims for losses of the kind, asserted the part was recently purchased when it had been in use for some time

and had deteriorated greatly in value.

W. B. Burpee secretary of the New Hampshire Insurance Co. of Manchester, N. H., was elected president of the conference to succeed George Bulkley of the Springfield Fire and Marine Insurance Co. of Springfield, Mass. John Marshall, Jr., of the Firemen's Fund Insurance Co. of San Francisco was elected vice-president, and F. W. Day was elected treasurer.

## DELAYS SETTLEMENT

PHILADELPHIA, Sept. 26—Insurance companies here writing automobile collision and fire policies are disturbed over the large losses that are being claimed this year and are taking steps to remedy the condition.

One of the largest automobile insurance underwriters in this district has discontinued altogether writing policies on four of the low priced machines. Another company has adopted the practice of delaying settlement until a thorough investigation of each loss has been made, in many cases this extending up to the full sixty-day limit.

Insurance brokers are making a more thorough investigation of the "moral hazard" involved in each case. A casualty company specializing in liability and property damage coverage reports the demand for this kind of insurance has been in excess of last year.

## HOLD BATCHELDER FUNERAL

NEW YORK, Sept. 27—The late Amos G. Batchelder, former executive chairman of the American Automobile Association, who was killed in an airplane accident on May 28, last, will be buried to-morrow at his old home at Attica, N. Y. The body will be taken from the receiving vault at Forest Lawn Cemetery, Buffalo, at one o'clock and carried over the new Batchelder Highway to Attica, where funeral services will be held in the Masonic Temple.

## Ford Is Reducing Accumulated Stocks

### New Manufacturing Schedule Adopted to Reduce Inventory Before Winter

DETROIT, Sept. 27—In the face of steadily increasing business since the price cut of Sept. 2, Ford Motor Co. has adopted a manufacturing schedule which will work off all surplus parts accumulated in the many assembly plants of the company before the winter months set in.

For the second successive Saturday, the Highland Park plant, in which all the parts are manufactured, was down. The company production officers deny that a five-day weekly working schedule has been determined upon, but only that this half day closing is to bring about an equalization of stock.

In addition to the half-day closing, however, employees in many departments are now working on alternate week shifts and have been notified that this arrangement would be continued for the present.

From the company's statement that working arrangements of this kind have been made for equalization of stocks, it is evident that considerable surplus has been accumulated in the rush of summer manufacturing, and that the company does not intend to carry this inventory over the winter. There is every indication, however, that operations will be continued on an ample scale for the balance of the year.

## MERIT MAKES REDUCTIONS

CLEVELAND, Sept. 26—The Merit Motor Co. has reduced the prices of its two passenger and four passenger models from \$2,245 to \$1,985.

# WALTHAM SPEEDOMETERS AND AUTOMOBILE CLOCKS

*Made for  
Motorists  
who Demand  
the Best*

THE Waltham is the only Air-Friction Speedometer in the world. Changes of climate and temperature do not affect it. It is instantaneous, accurate, and dependable in recording speed.

A speedometer is an indispensable part of automobile equipment.

Waltham Speedometers are specified as standard equipment by makers of such noted cars as Cunningham, Daniels, Fergus, Lafayette, Leach Biltwell, Lincoln, Packard, Pierce-Arrow, Renault, Rolls Royce, Stevens Duryea, Wills-Sainte Claire, and others.

Go to any automobile agency, representing any of these cars, and ask them to show you the perfection of its performance.

Waltham Speedometers and Automobile Clocks exemplify the minute genius for precision and dependability which has made the name of Waltham supreme in time-recording mechanisms.

More and more automobile owners are demanding the best in motor accessories for the added comfort, convenience and safety of those who may ride in the car.

Be sure that your car is equipped with a Waltham Speedometer—insist upon it.

## Foreign Automotive Markets Ripe for Attention

Appreciated exchange and growing recognition of the automobile as a utility awaken renewed interest in foreign trade. Plans must be made far in advance of actual business if future sales are expected.

By George E. Quisenberry\*

**D**URING the next few months the American manufacturers of automobiles and automotive equipment must determine their policies and their attitude in regard to international trade. With a gradual but none the less positive improvement in our foreign trade indicated by practically every report from the centers making up our overseas markets and with the exporters of automotive equipment generally sensing a coming resumption of business on a broader scale, the fixing of these policies and the methods of going after the trade assumes an immediate importance. Plans must be made now for business desired next summer.

Export markets have received little attention recently except from those few companies which overloaded their foreign dealers and faced rejected shipments or uncollected accounts in foreign ports. But other companies have given little attention to their overseas trading and are now confronting a time when their decision must be made. Time is pressing.

The domestic situation for months has been so difficult and so tangled that the manufacturers have had no time to devote any efforts to other markets. Foreign trade was accorded but little thought. This part of the business was due for a slump and the natural tendency of the manufacturers was to neglect it be-

cause of the seriousness of the domestic troubles.

But as the domestic situation has changed, so have the overseas markets. The home markets during the last four or five months have been larger than was expected, so that even the closest observers of the industry and those who best know its strength have been surprised. Car and accessory sales in many cases have exceeded expectations and the result has been a consequent lessening of the domestic worries.

Furthermore, international business has begun to pick up. This is shown by the July and August overseas shipments. July revealed an increase over June, so far as car sales were concerned, and August was better than July. The increases were small, indeed, but they were increases, none the less, and give promise of the better markets that may be expected as the year turns and as general business improves.

Foreign exchanges, leaving out those of Central Europe, have shown a steady appreciation for many countries. The pound sterling has appreciated materially and the improvement in some of the Latin-American currencies has been such that the pessimism in those countries has suffered a severe jolt. The Indian rupee and the Chinese currencies are advancing steadily and Bombay has come back into the gold market as a buyer, indicating a better and more

\*Managing Editor, *El Automóvil Americano*.

satisfactory financial condition in that great British territory. These straws in the winds of prophecy point the way that general business is going.

Mexico is a heavy buyer of automotive products and for some months has been the leader of all countries of the world. Cuba, despite the seriousness of the sugar situation, has not ceased to purchase. Peru, her stocks of cars wiped out during the summer centennial celebration, forecasts better conditions as cotton prices have gone upward. Brazil is making numerous purchases and dealers there have given every indication that cars will still be bought from those companies willing to co-operate in meeting the temporary exchange difficulties. The annual automobile show in Argentina will be held in late November and, with better wheat demand and advancing exchange, the unsold cars there should dwindle and open that market in the coming year. Already Ford has reported increasing business from Buenos Aires and the future appears much brighter, particularly since the \$50,000,000 Argentine loan was announced in New York.

Australasia is buying again and some business is moving to the Straits. South Africa, like Australia, is immensely helped by the betterment of the pound sterling and banking connections in that great section of the world report an improved financial condition. The Far East can be judged by the advancing exchange, the Shanghai tael and other currencies having risen materially as general commerce has bettered perceptibly.

In addition, ship space is in greater demand and the operators report, in their current journals, a larger volume of loading in many ports. The great wheat exports that have been going out of the North American ports since the harvest began indicate a similar movement from the other grain growing countries, such as Argentina, when their crops come in. These things, taken together with the statements of such responsible business men as Hoover, show that business as a whole has improved and that better conditions in foreign trade are in the making.

This upward trend means much to the automotive industries, whose foreign trade is just at the threshold of its development. The foreign markets in the developing countries of the world have seen no more than the start of their automotive purchases. In 1920, by counting Ford production in the various foreign assembly plants, the world purchased approximately 200,000 American-made motor cars and trucks, although few countries received anything like as many as would have been absorbed if delivery had been possible.

New uses for the automobile, the truck and the tractor are being found in these countries and new services opened up for them. Roads are being built and improved in countless sections in a greater amount than for many years. The automobile is being used as an essential and necessary means of transportation, its utility broadening so that it is no longer sold merely as a luxury. It is being put to work, doing its valiant part in upbuilding vast economic, industrial and agricultural resources in many territories.

That these territories have been under a business cloud for twelve months or more means nothing fundamentally and is no argument against their future trade in American-made automotive products. We have proved the automobile here at home and its worth in a thousand services has been so demonstrated that, even in the midst of such a year as 1921, production on a high scale has been necessary to meet the insistent demands of a public requiring transportation.

Why will not this same condition prevail in other countries of the world? These countries may not have realized the automobile fully as yet, they may be in the midst of a temporary depression that brings with it pessimism and gloom and, yet, having no more than scratched the rich natural resources that are theirs, it is inevitable that they shall have need for the transportation services of the automobile as we know it in America.

Thus, we have come to the immediate problem of the automotive manufacturer. Foreign business is ahead of him and destined to come his way if he will advance to meet it. The time was, perhaps, when it would seek him out. "Them was the days," we may say with regret, but we cannot expect them to return to-morrow

or the day after. The world has become shy and wise in parting with its dollars. The dollars are there, of course, and so is the buyer's appreciation of an honest product at an honest price, but those dollars can be coaxed out into the open only with fair dealing and honest service. Fundamental conditions have not changed, but the world has turned back to its pre-war state, realizing the worth of its money and demanding real value in return for it.

Foreign trade consists mainly of foresight and advance effort. It must be sought after and that to-day is of more importance than it perhaps ever has been. Work must be done long before the consummation of the business. The manufacturer or exporter cannot go out to-day and have a volume of business to-morrow. By going out to-day, with merchandising plans carefully made and forcefully followed, sales may be well under way in five or six months, but the time element must be considered. So it is not too early to start now after the trade that should come in next spring and summer from every corner of the world.

The problem of merchandising abroad does not differ materially from that at home. It is different only in minor points and the merchant who has a satisfactory domestic policy will also have a suitable foreign policy, provided the varying points are recognized and allowance made for them. These, after all, are only detail and need not affect the broad general principles of satisfactory service and fair dealing. Too many manufacturers think of foreign trade as something apart from their regular business, something mysterious and something shrouded in uncertainty.

Foreign trade is simply an extension of sales and sales effort across the national border lines and into another country. At bottom, trading methods in each section are similar and this may be especially stressed in view of the great body of automotive dealers who have

---

**R**ECENT years have thrown the American automotive industries into international trading. American-made cars and trucks have been distributed throughout the world. These export markets are re-opening. Can American makers hold them? How can they prevent this business from going elsewhere? These questions are fully discussed in this article which has been written after a careful study of present conditions.

---

been organized in the different foreign centers, a body of size and significance not generally realized. This development is taking place along the same lines as in America and the same factors apply to it. Consequently, successful firms at home can just as well go after foreign trade as domestic. With the facilities of service, information, credit ratings, etc., existing at present, manufacturers can go into this profitable branch of the automotive industry with full certainty that careful dealing on their part will be just as well received and just as productive of fortunate results as it would be in Pennsylvania, California or Texas.

World trade in automobiles and automotive equipment is again in the making. The post-war armistice period has passed and we are definitely progressing into the after-war development and prosperity. And the American manufacturer goes into this new period with the weather vanes all pointing his way.

Our cars and our equipment during recent years have gone to all parts of the world and the idea of the essential vehicle of transportation, efficiently produced and efficiently serviced, has attained a firm footing. Europe has but little competition worthy to challenge the automotive products from this country. No cars of the medium and lower-priced ranges are being built in Europe. It will be long before the proposed light cars being put into production by French and British makers are made in great enough quantities to be serious competitors from a price standpoint. Quantity production is practically unknown and the higher-priced cars of Europe are in competition with those of America only because the Europeans have been better at propaganda and sales efforts than have our own exporters. Certainly, no one who has had an opportunity to know, will admit that the high-priced products of the other

side are equal in quality to those built here and, that, despite the present conditions of exchange, price competition with the American products is possible in only a few countries and on only a comparatively small number of models. Conditions somewhat differ in the accessory and truck lines, but here again the question is largely one of propaganda and efficient merchandising effort.

Europe is building for foreign trade with passenger car shows in London, Paris, and Berlin. Much stress is being laid on the attempts of the continental manufacturers to build their cars along American lines. Production in these countries is, of course, freer than at any time since the war began, and the makers are now in a position to go after international trade. These factors must be taken into consideration by American manufacturers whose cars and trucks are to go into the foreign market against unlimited competition.

There are American automobile, truck and equipment companies to-day which are merchandising their products in the foreign fields with skill, fair play and intelligence. Our pioneer foreign traders have done their work well and their efforts are worthy of place among the best. These firms have no fear of the future of their export sales and they are just as keen on the foreign markets now as they were one, two or three years ago, knowing that this trade will take a considerable volume of production and knowing likewise that, with care and ability, a profitable and desirable business is assured in response to their foreign effort.

With these markets reopening, American factories must determine their stand on export trade and work out their policies in regard to it. Weeks and months are required to reach distant centers of distribution, and dealer organizations cannot be built up by the mere desire to have them. Something more is required—the business will and ability to go after the trade.

## S. A. E. Working on Material and Other Standards

THE Subdivision on Wrought Non-Ferrous Metal Alloys of the Society of Automotive Engineers' Standards Committee is considering specifications covering brass forging rod, brass spring wire, naval brass, or, as it is sometimes called, Tobin bronze tubing and phosphor bronze spring wire. If these specifications are adopted by the society, the S.A.E. Non-Ferrous Metal Specifications, of which there are now 25, will cover a sufficiently wide range to permit automotive vehicle designers to select standard specifications for practically any automotive purpose for which non-ferrous metals are used. The specifications proposed cover, in addition to the compositions in percentage specified, the physical properties, appearance, dimensional tolerances and general information of interest to engineers and manufacturers.

### Desirable Plate-Glass Practice

In many cases body designers have specified plate-glass window widths without regard to the commercial practice of manufacturing plate glass in even 2-in. widths. Waste can frequently be avoided by a slight change in the window design. It is, of course, cheaper to use a 19 $\frac{3}{4}$ -in. width in place of a 20 $\frac{1}{4}$ -in. width, because the first size can be made from 20-in. glass, while the second size is cut from 22-in. stock, since no intervening size is regularly manufactured.

Realizing this situation, a report has been formulated,

at the request of the Passenger Car Body Division of the S. A. E., which recommends that plate glass for automobile bodies shall be specified in even 2-in. widths in accordance with commercial practice if possible. It is also recommended that the thickness of plate glass should be specified in fractions of an inch, the maximum variations of thickness of any single piece of glass not to be greater than 1/32 in. in order to prevent the glass from being tapered. The report also recommends that the thickness of plate glass for windshields shall be  $\frac{1}{4}$  plus or minus 1/32 in. and the thickness of plate glass for closed body windows shall be 3/16 plus or minus 1/32 in.

### Pressure Gage Standardization

At the next meeting of the S. A. E. Screw Thread Division a preliminary report for pressure gage connections will be acted upon. The principal dimensions specified in the report are the diameter and the threads per inch of the air connection at the back of the instrument. The report has been approved by pressure gage, as well as passenger car and motor truck manufacturers. The general adoption of the recommendation will make pressure gages interchangeable, as there is already a standard for the outside diameter of the instrument case and the location of the holding screws, when these are used.

# Important Changes Feature the New Jordan Model

A new design of Continental engine, made exclusively for the Jordan company, incorporates chain drive and hollow shaft lubrication. Frame has been stiffened and several refinements in coachwork made. New single plate clutch is employed. Exposed metal parts are rust-proofed.

By J. Edward Schipper

**A**N entirely new Jordan car has recently been put in production. While the chief components are still manufactured by parts makers, most of them now are largely of Jordan design and are found in the Jordan car exclusively. An example is the new Continental engine, which will be made only for the Jordan.

While the foundation for the new design has been the previous Jordan model, many improvements have been made, and the resulting product differs materially from its predecessor.

The frame of the car has been stiffened. If the frame of the older model were laid on the floor and two men stood on one side rail it was possible to raise the other side rail 1 or 2 ft. before the side bearing the men was lifted from the ground. With the new frame, the flexure under the same conditions would be only a few inches. The result is a considerable lessening in the weave of the frame and in the tendency of the body to develop squeaks and rattles. This result has been accomplished by extending the maximum depth of the side rails over a much greater portion of the length and by the use of tubular cross-members at both ends. These cross-

members are secured to the frame by riveting through steel castings which project into the tube and are keyed to it. Improved riveting and gusseting of the cross-members has also added to the rigidity of the frame.

The new engine, which is made by the Continental Motors Corp., is supported at three points and is a block-cast, six-cylinder unit. The head, cylinder blocks and crankcase are cast separately; the flywheel housing is cast separately from the crankcase and is bolted to it. The cylinder head and cylinder blocks are of gray iron, and the crankcase and clutch housing are of aluminum. The engine is an L-head, four-bearing type of 3 5/16-in. bore and 4 3/4-in. stroke. The crankshaft is 2 1/2 in. in diameter, which is unusually large for this size of engine. This large diameter makes for rigidity of the crankshaft and prevents vibration. Freedom from vibration was evidenced by a test which the writer gave the car over varying roads in the vicinity of Cleveland. The compression pressure is about a 70 lb. per square inch absolute.

The cast iron pistons weigh 22 oz., are 3 15/16 in. in length and have three rings, all above the piston pin. The bottom piston land is chamfered and drilled to provide an oil drain. The piston ring widths are 3 1/16 in. and the piston pin diameter is 55/64 in. The piston pin bearing is in the top of the connecting rod, the pin being clamped in the boss and held by a lock screw which passes all the way through the pin and into the opposite side of the boss. In addition to this method of locking the pin, another safeguard against creeping is provided in the form of registering grooves into which a spring ring is inserted.

The connecting rods are of I-beam section,

Right side of Jordan engine showing mounting of water pump-distributor unit, water manifold and large filler-breather device

Front end of Jordan engine showing new triangular chain drive

10½ in. in length, and are machined all over. The crankpin bearings are 2¼ in. in dia., and the main bearings are 2½ in. dia., except the front one, which is 2¼ in. By making the crankpin bearings lighter than the main bearings, the torsional vibration of the crankshaft is said to have been materially reduced. The connecting-rod caps are secured by two bolts of alloy steel. The lengths of the main bearings are, front to rear, 2⅜, 1 9/16, 1 9/16 and 3 1/16.

#### Silent Chain Drive

A new departure for the Jordan company is the use of silent chain drive at the front end of the engine. It is a triangular layout, the Morse chain passing over the crankshaft, camshaft and auxiliary shaft sprocket. Chain adjustment is made by swinging the auxiliary shaft outward until the proper tension is applied on the chain. This adjustment is accessible and the units driven by the shaft are so arranged that they are not affected by the adjustment. This auxiliary shaft carries the fan pulley in front of the chain case. Immediately behind the case are the vertical distributor shaft (driven by helical gears), the oil pump, water pump and the generator, the latter driven through two flexible couplings. The distributor, oil pump and water pump all move as a unit when adjustment is made. The rubber hose connection for the water pump and the two flexible shafts for the generator permit sufficient movement of this shaft to make any necessary adjustment of the chain without affecting the water feed or the generator drive. The forward part of the water pump body and the oil pump housing are in one casting, which gives a very compact arrangement and fits in well with this type of auxiliary drive.

The camshaft is mounted in four bearings, whose diameters and lengths are, front to rear: 2 5/16 by 2 3/64 in.; 2 9/32 x 1; 2¼ x 1 and 2 7/32 x 1 5/8 in. The valves have 1 43/64 in. outside diameter and a lift of 5/16 in. and are operated by mushroom followers. The engine is timed to fire 1-5-3-6-2-4, and the valves are timed so that the exhaust opens 40 deg. ahead of the lower center and closes at 8 deg. past the upper center,

while the inlet opens 12 deg. past the upper center and closes 40 deg. past the lower center. The entire valve layout is designed to be particularly accessible. The valve tappet guides, for instance, can be removed without taking off the cylinder block, being held by clamps which are accessible when the cover plates are removed.

Water circulation is by centrifugal pump. The water system has a capacity of 4½ gal. The radiator is a Sparks-Withington cellular type and is supported in an original and interesting manner. It rests in a cradle consisting of a strap which passes entirely around the shell and clamps at the frame line. This method of mounting the radiator is similar to that employed in mounting the gasoline tank and seems to work out very satisfactorily, particularly in that it distributes the clamping stresses over the entire circumference. The water enters the engine jacket under the exhaust valves in two places and ample water space has been provided around the exhaust valves and spark plugs.

#### Hollow Shaft Lubrication

Oil feed under a normal pressure of 20 lb. to the sq in. is used for engine lubrication. The gear type of oil pump is driven from the bottom of the distributor shaft and forces the oil to a thin steel gallery tube which is cast in the crankcase. From this main tube there are feeder tubes to all main bearings where the oil passes into the hollow crankshaft. Drilled leads in the crankshaft conduct the oil to the crankpin bearings. The timing chain is lubricated by the overflow which is caught in a pocket at the front end of the main gallery tube and delivered directly over the chain. There is also a bleeder lead to the chain, and this unit operates continually in a bath of oil. The pressure regulator is located at the front end of the gallery tube and is easily adjusted to provide the proper tension on the spring pressure relief. An oil pressure gage is mounted on the dash and communicates with the rear end of the main gallery feed. One of the interesting points of the engine is the extremely large oil filler which is mounted at the front in such a way that oil can be readily poured into it without spilling. The oil passage has been made large enough so the oil may be poured into the crankcase as rapidly as desired. There is also a plainly visible dial type oil level indicator.

Fuel is carried in a 16-gal. tank of square section

Rear end of Jordan frame showing mounting for spare tire and gasoline tank, new filler cap with spring bayonet instead of thread, and non-rattling spring shackle

Sectional assembly of single dry disk type of clutch used in new Jordan car

Views of casting which encloses distributor gear drive and is part of swinging unit used to enable chain adjustment

mounted at the rear of the chassis between the frame rails. A new type of spring bayonet cap is used on the filler to prevent trouble with crossed threads. The gasoline is fed by vacuum to a 1¼-in. plain tube Stromberg carburetor. The intake manifold is a hotspot type, but somewhat less heat is applied than in the previous model, it having been found that in hot weather the power of the engine was slightly impaired by overheating of the intake. The new hotspot constitutes a compromise which is said to meet summer and winter operating conditions equally well.

Delco equipment is used for starting, lighting and ignition. The starter is mounted on the left side, with a pilot type mounting, and the generator on the right side at the end of the auxiliary shaft, as described. A separate pad is bolted to the crankcase and the generator is mounted on this pad.

The clutch is a new dry, single-plate type manufactured by the Detroit Gear & Machine Co., which concern also makes the gearset. This latter is a three-speed, selective unit, and has been improved from the driver's standpoint by lengthening the shifter lever. The ratios in the gearbox are 3.2 to 1 on low, 1.72 to 1 on second and 3.88 to 1 on reverse. The drive is through a hollow propeller shaft with two Spicer type universals. The rear axle is a new Timken floating design. Following a recent tendency in axle design, this new axle has a bearing on both sides of the pinion, supporting the pinion shaft. It is a spiral bevel type, providing a ratio of 4 2/3 to 1 for the closed bodies and 4 5/12 to 1 for the open bodies. The car is mounted on semi-elliptic springs 37 x 2 in. long in front and 56¼ x 2 in. long at the rear. A Gemmer steering gear is fitted.

While the new bodies are not materially altered in outline, they are considerably changed in detail and fittings. They are all mounted on the standard 120-in. wheelbase chassis. The standard tire size is 32 x 4 in. Some of the body details are novel and interesting. For instance, the louvers in the hood, instead of being on the outside, are on the inside, which is claimed to more effectively draw in the air from beneath the hood.

Close attention has been given to rust-proofing of the car. Practically every bolt and screw on the exposed parts of the body is of nickel-plated brass. This also applies to a large percentage of the hardware. The parts which are necessarily made of steel have been Parkerized.

The entire front compartment has been rearranged. There is a new instrument board in which all of the instruments are under one glass. The board has been cut away at both sides so as to provide a greater amount of knee room for the driver and the front seat passenger. The starting switch is now located on the toe board instead of near the front seat, so that

it is impossible for anyone to accidentally step on the starter button when entering the car. The switch plunger itself has a mushroom type head which prevents water from entering the switch parts.

Much has been done to prevent rattles and other noises about the car. The muffler is now a two-compartment instead of a single compartment type. The muffler tail pipe has been extended to the rear of the body so as to prevent any chance of exhaust impulses giving a drumming sound, particularly in closed bodies. The Jordan anti-rattle shackles, which are held under spring pressure, have been improved and are used on both the front and rear springs. The dashboard, which separates the engine compartment from the body, is backed with non-sonorous material to destroy resonance.

Grease cups, in more or less inaccessible positions, have been eliminated and oilless bushings substituted

wherever practical; where they are not practical, as on the brake shaft, a lead of flexible tubing has been brought back and clipped to the rear spring so that the Alemite attachment can be readily applied. The front end of the drag link, which was formerly packed with grease when assembled and not provided with any further lubricating means, has now been provided with an Alemite attachment.

#### Detail Refinements

The small tools are now carried in a compartment in the left front door, which is provided with a steel door and padlock for protection. The tools are snugly fixed in the door so that they cannot rattle. A transmission lock projects above the floorboard and permits of locking the transmission in neutral by pushing down on the lock. The top is now secured to the windshield by means of a nut which gives a positive, non-rattling anchor. There is a cowl ventilator to cool the front compartment and the windshield has been made rain-tight by a new form of rubber stripping. The side curtains have been taken out of the top pocket and put in door compartments.

To render the seats more comfortable they have been lowered and tilted at a greater angle. Marshall cushions are employed.

The brake centers have been very carefully laid out so that the flexure of the spring does not affect the position of the brake pedal and brake lever on rough roads.

Jordan prices are as follows: Five-passenger touring car, \$2095; roadster, \$2,095; brougham, \$3,200; sedan, \$3,200; landaulet, \$2,595.

## Britons Agree on Type of Car for Export

**B** RITISH manufacturers, at a recent conference, agreed upon certain standards in building cars for export, some apprehension being felt in some circles over the slackening of foreign business. Pessimism was expressed at the meeting over the question of cost and it was realized that until labor and material were cheaper and methods of production improved upon England would be compelled to put forth strenuous efforts to keep pace with its competitors in motor exportation.

In agreeing upon the type of car to be exported the manufacturers decided that the chassis should be strongly sprung, with detachable wire wheels fitted with wide tires. The clearance should be at least 8 inches for small and 9 for large cars. The wheel track should be from 4 ft. 8 in. to 4 ft. 9 in. Less would mean that cars could not be run on the many back-country roads that are generally little else than parallel cart-ruts.

The ratio of power in the engine should be 1 hp. per cwt. of the completed vehicle. Detachable cylinder heads should be fitted. The radiator should be large, and the fan capable of varying speeds. The gasoline tank, with a

vacuum feed fitted, should be in the rear of the car. Lubrication should be by pressure feed. Magneto ignition is preferable, and the lighting system and self-starter should form part of the chassis. Gearing should allow of much hill-climbing on top speed. The rear axle should be of the full floating type, and the brakes and steering particularly strong.

In finishing, brass fittings should be cut out as far as possible, to ensure a minimum of cleaning. The body should be despatched minus the last coat of varnish. Thus freight damage can largely be put right after the car is unshipped. Plenty of elbow-room should be allowed for, as commodities as well as passengers would be carried.

**I** N a paper read before the Academie des Sciences, M. Mailhe described a process for manufacturing motor fuel from linseed and other vegetable oils by passing the vegetable oils over a special apparatus which deprives the oil of its water and hydrogen. The resultant volatile product is then passed over nickel, and M. Mailhe claims that it is then in all respects similar to gasoline.

# New Commercial Airplane Designed in Europe

Rearward stagger of the wings a new feature as is a rectangular section fuselage containing a five-passenger cabin with pilot's cockpit forward. Although plane is of French design a 420 hp. British engine is used. New model embraces many features of other machines of same make.

By John Jay Ide

**A**MONG the foremost airplane designers in Europe to-day are the two directors of the Nieuport company—MM. Delage and Bazaine. In the design of the Model 29-C-1 pursuit machine and its development, the winner of the last Gordon Bennett race, they have added fresh laurels to the firm founded by that great genius, Edouard Nieuport. Had the war continued the 29-C-1 would have replaced the Spad XIII as the standard French single-seater fighter.

The latest product of the Nieuport company is the Model 30-T commercial airplane, equipped with a British Sunbeam "Matabele" 420-hp. engine. The reason for choosing a British engine is not known, unless it be that there is no French engine of the required power in production. There are a number of points in the design of the Model 30-T reminiscent of the earlier models of the firm. Among these are the ailerons on the lower wing only (undoubtedly the most efficient position when flying very low), the landing gear and the method of engine cooling by twin Lamblin radiators (described in *AUTOMOTIVE INDUSTRIES*, Oct. 21, 1920).

New features include the rearward stagger of the wings and the rectangular section fuselage containing a cabin for five passengers and a pilot's cockpit forward. The cabin is very comfortable and has good visibility, thanks to its eight windows.

## Twelve-Cylinder Engine

The engine is of the 12-cylinder V type, developing 420 hp. at 2000 r.p.m. of the crankshaft and 1225 r.p.m. of the 4-bladed propeller. The cylinder dimensions are 4.8-in. bore and 6.3-in. stroke, giving a volume of 1368.7 cu. in. The weight of the engine with water but without fuel or oil is 1091 lb. The engine has two Claudel carbureters, the air being obtained by a scoop on each side of the fuselage, and the vertical exhaust pipe will be noticed.

The rod attached to the two outboard struts on the starboard side was used to carry the Pitot tube for indicating speed during the trials. Normally, of course, the speed is registered by means of the twin tubes seen on top of the upper plane amidships. Originally all control surfaces were balanced. After preliminary trials, however, the balanced portions of the ailerons were cut off.

The characteristics of the Nieuport 30-T are as follows:

Span (upper wing) .....	50.8 ft.
Span (lower wing) .....	47.5 ft.
Gap .....	8.5 ft.
Chord .....	8.5 ft.
Wing area (incl. ailerons) .....	700 sq. ft.
Aileron area .....	60.8 sq. ft.
Stabilizer area .....	64.6 sq. ft.
Elevator area .....	36.6 sq. ft.
Fin area .....	10.8 sq. ft.
Rudder area .....	15.1 sq. ft.
Weight (empty) .....	3300 lb.
Useful load .....	1980 lb.

(Including 550 lb. of fuel and oil)

Total weight .....	5280 lb.
Wgt./sq. ft. ....	7.5 lb.
Wgt./hp. ....	12.5 lb.
Speed .....	107 m.p.h.
Endurance ... ..	5 hours

It will be noted that the propeller used is of the four-blade type and is geared down to run at about five-eighth engine speed. The cowl which covers the engine has a characteristically French appearance. Carrying the exhaust pipe

upward to about the level of the upper wing tends to muffle the noise of the exhaust and render it less annoying to the passengers. The Lamblin radiators referred to above are the torpedo shaped objects below fuselage.

## Automotive Duties in Czechoslovakia

**T**HE Parliament Czechoslovakia will shortly discuss a legislative scheme concerning the increase of import duty on automobiles and parts of automobiles. According to this bill, the import duty will be augmented, for countries to which the general tariff (autonomous) applies, by 90 per cent. of the invoice price; for countries to which a special tariff applies, 65 per cent. of the invoice price. For motor engines and motor ploughs, tractors, locomobiles, and motor boats the duty will be determined according to weight: up to 50 kilos, 6000 crowns as minimum tariff, 7500 crowns for the general tariff; from 50 to 250 kilos, 5500 crowns minimum tariff, 7000 crowns general tariff. Aeroplane engines, without distinction, will be subject to the following duties: 15,000 crowns each, minimum tariff; 20,000 crowns each, general tariff. This increase in customs duties is caused by the fact that the present tariffs do not protect home production, and bear no comparison with analogous duties levied by France, Italy, Great Britain, and the United States.

A recent design of Nieuport 5-passenger airplane

# Manufacturing Possibilities Offered by Duralumin

There has been much discussion concerning the properties and uses of duralumin. This article presents a critical analysis of the manufacturing possibilities of this copper-aluminum alloy. It has been written as a result of considerable experimental and research work.

By William B. Stout\*

**T**HE new light alloy duralumin can be rolled into sheets or forged by hand, press or power hammer.

It can be cast, welded and soldered, while rivets of the same material used with it show new production possibilities, on account of the peculiarity of the heat treatment results. Connecting rods have been made of it, using the metal itself for wearing surface without anti-friction metal. These have operated successfully in both motor cars and aircraft engines. Worm gears have been made of "dural" (as it is colloquially called) and used in heavy truck service successfully against steel worms. Timing gears of this metal show new possibilities of both wear and quietness, but most use has been made of the alloy in structural shapes for ultra-light constructions. The metal itself costs about five times as much as cold rolled steel per pound. For production work, however, only one-third the number of pounds is used for the same strength result, and since the material is much easier to work than steel in most of its forms, it saves materially on labor, tool cost and tool depreciation, so that in many cases constructions can be made cheaper of duralumin than of steel.

Structures are now being built of duralumin which far exceed former strength figures in wood and yet are lighter than any previous wood-and-cloth airplane constructions. We have at present in process machines capable of carrying twenty passengers at two miles a minute for five hours, and fitted with 600 hp. engines, yet the whole machine weighs no more than a Cadillac touring car. It is safe to state that the low weight figure could not have been reached with our present knowledge with any other material.

## Stronger Than Steel in Structures

Many have preferred steel in their experimental aircraft work, for the reason that steel exceeds duralumin in tensile strength even after allowing for its greater weight. But the problem of strength in a structure does not always depend on the properties, but often on the column or compressive strength.

For the same weight, duralumin has about three times the thickness of even its cold-rolled boiler-plate counterpart, and five or six times the section of alloy steels of high tensile strength. The rigidity of a sheet is dependent on its thickness very largely, and, while "dural" is a much more flexible material than steel in equal sections, yet with the greatly increased sections used for equal strength a much greater rigidity is obtained than with steel.

For example, we have produced a rolled section designed for a maximum column strength and yet of such shape as to fit production requirements. This section of 0.035 in. thickness of metal in a 19-in. column weighs 7½ ounces and will support a weight of over 4 tons. If made of high-tensile alloy steel, its thickness, so far as tensile requirements go, would be about 0.009 in., but this would be untrustworthy in a structure on account of the lack of rigidity of such a thin wall.

## Physical Properties

Duralumin looks much like aluminum, except that it takes a high polish and that, when polished, the glinting red of the copper in the alloy can be detected. In ordinary atmosphere the polish is permanent, the metal being non-corrosive to a very high degree. In the tempered state it is almost immune to the effects of salt spray, though in the annealed form salt water affects it.

The chief difference between this and previous aluminum alloys is that its physical characteristics are materially changed by proper heat-treatment. The most peculiar thing about the metal is that the change in physical properties following heat-treatment is not instantaneous but very gradual, attaining a maximum after about four days. During this period not only is the tensile strength increased 50 per cent or more, but the elongation increases from 600 to 800 per cent. More than this, in its heat-treated form the metal can be reheated and softened for passing through mechanical processes not of too violent a nature, and at the end of one hour it will have resumed its original tempered characteristics. The fact that the extreme properties of the metal are not reached immediately, as in most metals, is of great advantage commercially, as will be explained later.

The heat-treatment or tempering of the metal consists in heating to 920-940 deg. for from 7 to 30 minutes, the time being governed by the bulk of the parts. The material is then quenched in boiling water. It is then removed from the quenching bath and worked as soon as possible. In from one to two hours' time the metal acquires sufficient hardness so that it is difficult to work.

In our airplane work we heat-treat a coil of sheet metal in a bath of sodium and potassium nitrates, quench in an adjacent tank of boiling water, uncoil the sheet or strip and start it immediately through the rolls which form it into the shape desired. The process is completed and the spar ready for aging within 20 minutes.

Duralumin is a copper-aluminum alloy, the copper content running about 4 per cent. Some magnesium is also present, and zinc is the most detrimental im-

\*Digested from a paper read before the American Society for Steel Treating.

purity. For this reason duralumin is made only from the purest 99 per cent aluminum, so that the impurities in the various elements of the alloy will not build up a detrimental quantity. It is the inability of the Germans to obtain pure aluminum which has prevented their duralumin alloy from equaling the figures obtained in every-day production from the American product.

The metal itself, however, was developed in Germany from an original French laboratory development. The first real commercial use to which it was put, so far as the public was concerned, was in the metal ships of the Zeppelin company. One of the reasons for the slow development of the Zeppelin, aside from the problems of airship design itself, was the necessity of developing the metal along with the structure.

At first considerable trouble was had with corrosion. Sheets granulated, seemingly without reason, and until the difficulties were worked out, structures built of the material were more or less unreliable and required frequent inspection. This is still true in very thin gages not carefully heat-treated, but with pieces of any real section corrosion is now an almost unheard of thing.

#### Troubles Due to Impurities

The main troubles with duralumin are similar to those with other alloys, being due to the presence of impurities in the ingot or to air bubbles, which later cause serious defects when the piece is forged or rolled.

Most of our material is of 0.035 in. thickness, so that a very small speck of dirt can make a serious flaw in the metal sheet and a very small air bubble a considerable pipe in the center of the sheet.

Most of these flaws do not show up until after the rolling. In this case the greatest stress on the metal in putting it through the rolls is at a hidden point, so that to inspect these spars or chord members a dental mirror is used with a high light, and the surface very carefully examined. Frequently a hole as small as the point of a fine needle can be opened up into a flaw 5 in. long—a sort of stratification of the metal—resulting from original ingot impurities.

In the design of the rolls, also, great care must be taken against too great a degree of draw between annealings, and that all radii must be sufficient for the requirements of the metal.

The great drawback of the material as we are using it at present is the presence of ingot flaws, rolled out in the sheet, which lead to a very high rejection cost. When this is cured the experimental stage of duralumin will be over. As soon as large quantities of the material are demanded rolls can be put in for greater widths of sheet than at present available—16 in. being now the best obtainable—and tubing and other structural forms will become available.

Composition: Copper, 3.50 to 4.00 per cent; magnesium, 0.20 to 0.75 per cent; manganese, 0.40 to 1.00 per cent; aluminum (99 per cent pure) balance.

Physical properties: Specific gravity, 2.80; weight, 0.102 lb. per cubic inch; melting range centigrade, 540 to 650 deg.; compressive strength tempered, 44,000 lb.; sheet value tempered, 30,000 lb.; tensile strength tempered, 50,000 to 60,000 lb.; elongation tempered, 16 to 20 per cent; modulus of elasticity, 10,600,000; coefficient of expansion, 0.0000226 per deg. C.; yield point, 30,000 lb.

## Piston Temperatures

RESULTS of an experimental investigation of the temperatures at different points of a Diesel engine piston under different loads and with different fuel injection pressures are published by Dr. Eng. W. Riehm in *Zeitschrift des Vereines Deutscher Ingenieure*. The results will undoubtedly be of some interest to automotive engineers, in so far as they show the temperature gradient through the thickness of the piston head at the center, along a radial line from the center of the piston head outward, and down the skirt. The temperatures were measured with thermo-couples set into the walls of the piston at different points. One joint of the thermo-electric couple was located at the point whose temperature was to be measured and the other joints of all couples were placed in a heat-insulated box secured to the piston head. From this box a multiple-insulated cable, made up of very fine copper wire, extended down the inside of the piston skirt and along the walking beam of the air-pump drive to the outside to a galvanometer. In this way a reliable electric connection from the moving piston to the galvanometer was obtained, which proved very serviceable and always lasted for several days before one of the fine copper wires broke. The temperature of the second joint in the heat-insulated box was measured by a special thermo-couple.

The tests were made on a 70-hp., single-cylinder, four-stroke Diesel engine of 16-in. bore and 24-in. stroke, at 165 r.p.m. Two designs of piston head were used, of different thickness and different degrees of concavity, the object being to determine which of the two would best withstand the tendency to cracking at the center. The results obtained with one of the pistons are given in the diagram herewith. The piston-head thickness in this case is 2.085 in. and the length of that part of the piston shown is 8.4 in.

It will be seen that the maximum temperature occurs at the center of the piston head, as would be expected from theoretical considerations. When running under 10 per cent overload this temperature reaches about 900 deg. Fahr. It is rather doubtful whether such a high temperature ever occurs in an automobile engine, notwithstanding the much higher speed, because, in the first place, the temperature of combustion is higher in a Diesel engine, and, secondly, the very large size of the engine retards the flow of heat to the cylinder walls. The triple diagram clearly shows the heat gradients along an axial line through the thickness of the head, along a radial line on top of the piston head, and along the upper part of the piston skirt. The dotted lines drawn in on the piston section are isothermal lines at the temperature marked thereon.

Results of temperature tests

# Headlight Regulation Discussed at Meeting of Illuminating Engineers

Education of motorists with regard to proper adjustment of headlamps one of the most important factors for improving conditions of night driving. The Massachusetts law was fully explained with examples as to the method of enforcement. City testing stations are valuable.

By P. M. Heldt

FROM discussions before the Illuminating Engineering Society, which held its fifteenth annual convention at the Powers Hotel, Rochester, last week, it appears that at present the chief problem in connection with safe and efficient headlamp illumination is the intelligent enforcement of the laws, particularly as regards the focusing of the bulbs in the reflector and the correct aiming of the lamps. Under the laws based on the I. E. S. headlamp specifications certain anti-glare devices are given approval for use in connection with bulbs of a certain candle-power, but it is realized that the use of such devices does not in itself insure efficient and safe lighting. It remains for the operator to see to it that his bulbs are properly focused, that the reflectors are maintained in a state of efficiency, that the lenses, if of the prism type, are not rotated in the headlamp shells and that the headlamps are properly aimed or directed. In some of the cities of the Middle West official headlamp adjustment stations have been established, and this seems to be the best solution of the problem. The I. E. S. system of headlamp regulation has been adopted as a standard by the S. A. E. and is undoubtedly familiar to most readers.

## Wider Application of Standard Regulations

At the meeting the annual report of the Committee on Motor Vehicle Lighting was presented. In this it was stated that since the last meeting the I. E. S. system has been made the basis of headlamp regulation laws in the states of Nebraska, Iowa, Utah and Ohio, while Massachusetts had adopted the system in principle but had written somewhat different specifications for tests. The committee stated that on the basis of registration figures published in AUTOMOTIVE INDUSTRIES about 43 per cent of all the cars in use in the country were now operating under laws based on the I. E. S. system, as compared with 25 per cent last year. The Province of Ontario also had adopted the system, and 42.5 per cent of the total registration in the Dominion of Canada were thus operating under the I. E. S. system.

It had been suggested to the American Engineering Standards Committee that the I. E. S. specifications be adopted as a tentative American standard, and this matter is now pending. It was learned that the International Commission on Illumination had adopted a resolution to the effect that headlamp regulations should be framed on the basis of an international agreement, so that the regulations would be uniform for all countries. The Commission established a study committee on the subject of automobile headlights, which is to report at the next session of the Commission. This study committee, of

which Dr. C. H. Sharp of the I. E. S. is president, is to draft technical proposals suitable for international adoption and to use the influence of the International Commission to convince the authorities of the different countries of the importance of uniform regulations throughout the world.

## Proposed Change in Tests

During the past year most of the work of the I. E. S. Motor Vehicle Lighting Committee had been in connection with details, but one definite change in procedure in connection with the tests of lenses was proposed. Up to the present two pairs of a certain size of lens had been tested with both 15 cp. vacuum and 21 cp. gas-filled lamps. It was proposed that in future the tests should be made with gas-filled lamps only, but that one pair of each of the four sizes of lenses standardized by the S. A. E.—namely, 8 5/32, 8 1/2, 9 and 9 1/2 in.—be tested. The object of the change was to make the results of the tests more representative of the device, since different molds were used for the various sizes.

The report concluded by stating that conditions on the road in night driving were becoming notably better. Complaints of excessive glare were still being received, however, and sometimes the complaint had been made that the work of the committee was futile, because it had not resulted in a more radical improvement. The committee submitted, however, that such criticism was not necessarily just, as its work extended only to a certain point. Lamps accurately focused or aimed might, even with the best of devices, produce an intolerable glare or an abominably low illumination, or both, and it was evident that the results on the road were to a great extent dependent upon the education of the motorist with respect to the proper adjustment of his headlamps and on the officers of the law to whom the enforcement of head-lighting regulations was intrusted.

Among items for future consideration by the committee are the determination of a standard for the illumination of rear license plates and the illumination of stop and turn signals. It was stated that there is a real need for an authoritative booklet on the proper adjustment of headlamps and on simple methods of checking the illumination to see if it conformed to the specifications.

## New Massachusetts Regulations

A. W. Devine of the Massachusetts Department of Public Works read a paper on Motor Vehicle Headlighting in Massachusetts. He said that in that State the much-copied regulations of Oct. 27, 1915, remained

in force until Aug. 15, 1921. These called for sufficient light directly ahead of the vehicle to make objects 150 ft. ahead clearly visible; for the absence of dazzling rays 3.5 ft. or more above the ground, 50 ft. or more ahead of the vehicle, and for sufficient side illumination so that any object 10 ft. to the side and 10 ft. ahead of the vehicle could be distinguished.

Hundreds of motorists were prosecuted under this law and substantial fines were imposed. The method of enforcement was as follows:

The officer would select a point on a straight, level, unlighted roadway from which approaching vehicles were visible for a distance of an eighth of a mile in both directions. From this point he would measure off 50 ft. in both directions, and would observe the light from approaching vehicles from the time they came into view until they were within 50 ft. of him, in the meantime walking back and forth across the road so as to observe the approaching light more carefully. To avoid the possibility of mistakes only vehicles with specially glaring headlamps were stopped. Operators of machines on which no attempt had been made to regulate the light were summoned into court for violation of the regulations, and in practically every case were fined.

Such enforcement was often preceded by educational work. On certain nights in different parts of the State motorists were invited to congregate at certain points and have their lighting equipment examined by a competent inspector who pointed out defects and faulty adjustment and advised regarding methods of correcting the defects.

As time went on it became apparent that the regulations were not very effective any more. All kinds of glare-eliminating devices were used, some very inefficient, and the lower courts would accept the statement of police officers only if no evidence was introduced to show that an attempt had been made to reduce the glare. The Highway Commission realized that it was not merely a question of the device used, but almost wholly a question of the adjustment. Therefore, on Dec. 1, 1919, when the Highway Commission was absorbed by the larger Department of Public Works and a Registrar of Motor Vehicles took over all the powers of the Highway Commission having to do with motor vehicles, it was decided that something should be done to correct the lighting situation.

Frank A. Goodwin was appointed Registrar of Motor Vehicles, and he detailed Mr. Devine to make a thorough study of the head-lighting problem. The latter first made laboratory tests on the light distribution obtained with some thirty non-glare devices, using a pair of accurate paraboloidal reflectors of 1 3/8-in. focal length, bulbs of 21 mean spherical cp. and 9 and 9 1/4-in. lenses. Following this, road tests were made over a period of several months, the lamps under test being mounted on universal brackets so that aiming tests could be made, and another pair of headlamps mounted beside them for the sake of comparison.

#### Road Lighting Requirements

As a result of these tests and the experience of the investigation department, it was determined that a minimum spread of beam sufficient to cover a 12-ft. roadway would be required for the safety of the users of the

highway. It was also determined that the I. E. S. specifications for glare limits were reasonable, and no attempt was made to modify them. These limits are: 2400 cp. max. at a point 100 ft. ahead of the car, 5 ft. above the ground, and 800 cp. max. at a point 7 ft. to the left of that point.

The next step was to determine what intensities should be required in different parts of the beam. The I. E. S. specification for road performance required a normal illumination of 0.12 foot-candles at the A or B and E or F points. This value was found to be a low minimum in actual road tests, particularly so in the case of a number of devices with which it was almost impossible to see an object illuminated to a corresponding brightness because they projected a beam of rapidly varying intensities from one point to a nearby point. In view of the fact that the Headlight Committee had established such a low and unusually fair minimum, it was felt that it would not be acceptable in making laboratory tests. Road tests and laboratory tests compared showed that under fair conditions of actual use the depreciation in lighting equipment would cause a reduction in illumination of about 50 per cent, as a result of a decrease in the reflection coefficient of the

reflector, a decrease in the impressed voltage on the lamps and deterioration of the lamp bulbs. For this reason it was decided that, as far as the laboratory tests were concerned, the requirements of the I. E. S. specifications for road performance should be doubled and an illumination of 0.25 foot-candles be called for at such points as it was decided to make tests.

In the application of these regulations headlamps are ordinarily mounted at a height varying from 34 to 38 in. above the ground, but for purposes of laboratory test the lamps were assumed to be at a height of 42 in. above the ground. This assumption results in greater freedom from glare in practice, but if not corrected for in computing the required minimum intensities in the beam would mean that those devices which complied with the specifications would not necessarily have sufficient spread to cover a 12-ft. roadway as desired. For this reason those minimum laboratory test points were selected which, with the centers of the lamps at an assumed height of 42 in. would indicate the parts of the beam which strike the edges of a 15-ft. flat roadway, or, under average actual conditions, would indicate the parts of the beam which strike the edges of a 12-ft. roadway. The P and Q points are those points in the beam which strike the edges of a 12-ft. roadway 115 ft. and 57 ft. respectively ahead of the car when the lamps are 36 in. above the ground. The M point is the test point at which is measured the intensity directly ahead of the car 1.25 deg. below the horizontal. This point is 0.25 deg. lower than the society's B point. Retention of the B point would have required 10,000 cp. and would have caused several satisfactory devices to fail to comply with the specifications. Furthermore, it might have resulted in the design of devices with too sharp a cut-off or which approached the glare limits at C and D too closely, resulting in excessive glare when the molds in which the lenses are made had worn slightly. It was felt that illumination up to a distance of 200 ft. ahead was not necessary for safe driving at a reasonable speed. The new regulations were drawn to call for

---

**A** RADICAL change for the better in night driving conditions cannot be effected until police officers charged with enforcement of the law and the car drivers are educated as to proper methods of lighting. In Massachusetts enforcement campaigns were often preceded by meetings of motorists where lighting systems were examined and experts explained methods of correcting the defects.

---

illumination up to a distance of 160 ft., an increase of 10 ft. over the old regulations. The wording of the specifications for laboratory test was taken from the society's specifications with a few changes. These specifications were given in part in Mr. Devine's paper.

#### Method of Enforcement

Considerable thought was given to the method of enforcement to be employed before formulating regulations. The use of a portable photometer in testing the road performance of lighting equipment was not considered entirely practical, and it was finally decided that the use of double specifications (road and laboratory) was undesirable. To secure compliance with the law it would be necessary to educate the public to make proper adjustments under any system, and adding the use of a photometer only complicated the problem.

The alternative method then suggested itself that enforcement could be had on the basis of condition and adjustment of equipment. A bill was introduced and adopted that "No headlamp shall be used upon any motor vehicle \* \* \* unless such lamp is equipped with a lens or other device approved by the registrar, designed to prevent glaring rays."

Regulations were drawn up requiring that headlamps be used on insufficiently lighted ways, that every approved device be applied and adjusted as required by the registrar's approval, that light sources of 21 cp. only be used and that any reflectors used as a part of such headlamps should have highly polished silvered or glass reflecting surfaces. These regulations went into effect on Aug. 15, 1921.

Other states have limited the maximum candle-power which can be used, and in Massachusetts it was felt that it was necessary to set a minimum candle-power as well, in order that the motorist might not be troubled so much by insufficient illumination. By standardizing on one size of light source, the contrast in the illuminated fields ahead of two vehicles is reduced to a minimum and, besides, there are advantages in the elimination of the many sizes of electric bulbs which dealers have heretofore stocked. In interpreting this provision, if a bulb of 21 rated cp. were used, a reasonable variation in candle-power above or below this figure would not be a violation of the regulations. In addition to the requirement that only 21-cp. light sources be used, all approvals of electric headlamp devices which have so far been issued require the use of a type C (gas-filled) bulb. This requirement is made not only to further standardize on equipment, but also on account of the higher efficiency and slower depreciation of the type C bulb. The new law in Massachusetts calls, then, for the use of an improved device, 21-cp. type C bulb (in electrical equipment), highly polished reflectors and proper adjustment of the device.

#### Tests of Lighting Devices

Forty-three applications for approval of electric headlighting devices were received and tested up to Aug. 15, 1921. Of these, 26 devices were approved for use; of the devices which were not approved 14 failed to comply with the limiting test intensities and 3 devices were refused approval, although they complied with the limiting intensities. Two of the devices which were

refused approval were deemed to be unsafe for use on account of unduly dark and bright areas within the area outlined by specific points, and one was refused approval because of unduly difficult and complicated adjustment.

The results of the tests of devices for approval clearly show that the requirements are much more severe in Massachusetts than in states which have adopted the society's specifications. Much importance is attached to sections reserving the right to refuse approval of any device which, although it conforms to the specified limiting intensities, is liable to prove unsafe because it does not comply with the intent of the specifications or unsatisfactory because it has an unduly complicated adjustment.

#### Focusing Device for Private Owners

Education of the motorist to the necessity of making proper adjustment of his headlamps and keeping his lighting equipment in good order is of prime importance. A novel method of educating the public is being used. A circular disc of heavy paper, perforated with two 0.25-in. holes, spaced 4 in. apart and equally distant

from the center on the same diameter is being issued. On this disc is printed the requirements of the law, the approved list, and focusing and aiming instructions. The disc is used for focusing the lamps by holding it in front of the lamp being focused without the device in place. Two filament images are projected on a vertical surface 25 ft. from the lamp, one image from the top part and one from the bottom of the reflector. The relative position of these images, one to

---

**E**XPERIENCE has shown that glaring and blinding headlights usually result from improper focusing. Motorists who have neither the inclination nor ability to adjust their lamps would be benefited if stations were installed in their home city, where experts could periodically examine their lighting equipment and adjust it to conform with required standards. This method has been successfully used in several cities. Some of the devices that have been used are described in this article.

---

the other, determines the focal adjustment. This focusing disc has met with great popularity, so much so that some difficulty has been experienced in supplying the demand.

Another important consideration is that for persons who have not the inclination or ability to adjust their own lamps, some place should be available where they can go to have the lamps adjusted. For this purpose complete printed instructions are being issued and competent persons who have the proper facilities are being approved of. Eleven trained inspectors from the Registry of Motor Vehicles are traveling throughout the State instructing and examining mechanics and others who seek official certification of their competency.

#### Tests on Illumination Requirements

Another paper was presented by H. H. Madgsick and R. N. Falge of Nela Park, Cleveland, and dealt with "A Determination by Various Drivers of the Desired Road Illumination from Automobile Headlights." Data were presented showing the road illumination from headlight equipment as set in a moving car by a total of 13 observers, under various conditions of road surface, contour, boundaries, street lighting, weather, speeds, etc., with lighting facilities which afforded a considerable range of intensity and distribution. These data indicate in a general way the lighting required for safety and a moderate degree of convenience—that is, the lower limit of what might be termed good practice—for the more common road conditions. They are not sufficiently complete to permit an analysis of the effect

of each of the variable factors. A description was given of the equipment employed, together with an outline of the procedure followed in obtaining the data.

The authors stated that in considering data of this kind from the standpoint of lighting equipment for a car it must be borne in mind that, because of conditions beyond the control of the car owner, such as large variations in voltage at the lamp, departure from a perfect product in sockets, incandescent lamps, reflectors and cover glasses, and depreciation in some of these elements, the laboratory tests with selected equipment must in general show twice the intensity values which it is desired to insure that the car owner obtain at all times in service.

The data presented were, as already pointed out, what the observers considered the minimum desirable from the standpoints of safety and reasonable convenience in driving under the given conditions. A higher order of intensity was in every case considered to reduce the strain of night driving and to contribute to the safety and enjoyment of the driver and his passengers, while also minimizing the danger to other people on the road.

The discussion centered largely around the enforcement of headlamp laws. It was opened by John A. Hoeveler of Madison, Wis., who said that we are not getting the enforcement we should have. The police cannot handle photometers and the motorist is suspicious if such a device is being used on him. Therefore, testing stations are necessary. In Milwaukee such a station has been in operation for several months. At this station a testing board is rigged up on which there are four translucent bulls-eyes. The two upper ones are for the determination of the non-glare qualities of the lamps and the two lower ones for the determination of the road illumination power. These bulls-eyes are lighted up from behind, and two of them must show light and the other two dark in order that the lighting equipment may comply with the State regulations. The outfit is operated by two police officers, one of whom spots the cars and the other operates the photometric equipment. The whole installation was worked out by the illuminating engineer of the city of Milwaukee, and it was perhaps fortunate that the city had such an engineer, which insured that the arrangement and method of use were accurate and practical. The station will shortly be closed for the winter, but in the future may be operated throughout the year.

Motor vehicle officers send into the station vehicles that seem to produce an inordinate amount of glare. Service stations are being appointed throughout the city for making adjustments of the lighting equipment. A plan of this kind could be worked out in each community, stations being established, for instance, at the county seats, and there would be no difficulty at all in establishing such stations in the larger cities.

#### Developments in Ohio

Dr. Francis C. Caldwell of Columbus, Ohio, said that the lighting situation was particularly acute in the State of Ohio. There they looked upon Massachusetts as a pioneer in the regulation of headlamp illumination. Conditions in Ohio were probably more representative of those throughout the country than conditions in Massachusetts. A new law went into effect in Ohio on Aug. 15. It called (1) for a distribution of light adequate to properly show obstacles in the road 200 ft. ahead of the vehicle; (2) for tests and approval of glare-controlling devices by the Director of Highways, and (3) for the reduction of glare below a certain maximum. There

were no provisions for the enforcement of the law other than the regular police powers of the State. Until recently the control of motor traffic had been in the hands of the Director of Highways. This official has to look after a great deal of highway construction and, as a consequence, is over-burdened with work, which causes him to look upon the control of motor vehicle traffic more or less as a nuisance.

All tests are made with 21-cp. lamps at the Engineering Experiment Station, a State institution. The great problem in Ohio, as elsewhere, was to get people to adjust their glare-control devices properly, and this called for the establishment of test stations. In Ohio no State funds were available for the purpose, but people with commercial interests in lighting equipment were taking the matter up. In Cincinnati and Cleveland these people have induced the automobile clubs to get together with the police and provide the necessary testing stations.

#### Tilting Headlights

There was a strong demand for more light than allowed by the I. E. S. specifications. A tilting headlight would be approved regardless of what illumination it produced when in the non-tilted position. For this the driver was allowed to take the responsibility. One glare-control device was turned down because it gave a very unsymmetrical distribution, with the result that pedestrians on the sidewalk at the right-hand side would get much more than 800 cp.

One of the speakers taking part in the discussion stated that on a certain make of low-priced car on which the bulb is adjusted from the rear by means of a screw and the reflector is held in place by a spring, when the non-glare device is applied to the lamp the position of the reflector relative to the bulb is materially changed, which has a great effect upon the lighting efficiency of the lamp.

Dr. Louis Bell said that he was interested in Mr. Madgsick's paper and the indications it gave that greater illuminating power was required at high speeds. We could not expect pedestrians to wear a red tail-light like the British Tommies were compelled to wear just before the war when marching in column formation.

Mr. Davidson made the assertion that focusing stations were needed. In his locality it was the practice of the police to give motorists whose headlamps showed an inordinate amount of glare 10-day cards which instructed them to go to an adjusting station and have their lights properly adjusted and then come back and report to the police. If they did not come back within the specified time, the police would go out and get them.

Frederick H. Ford of Waupun, Wis., said that, as a lens maker, he would suggest the provision of focusing stations in small towns, located in vacant lots abutting a street. They should be so arranged that car owners could drive there at any time and see for themselves whether their lamps were properly focused.

One speaker pointed out that in some of the cheaper cars, which had headlamp shells of very flimsy material, the lenses were inadequately held and sometimes turned around their axis, which nullified all the good work that the society had been doing. Lawrence C. Porter of Harrison, N. J., stated that the Ford company had recently made a move that was greatly to be commended. In his State the agencies were required to paint on the garage a white rectangle and all cars sold by them had their lamps adjusted so that when the car was spotted at a certain distance from the wall and pointed in the direction of the rectangle the entire beam from the lamps came within the rectangle.

# New Gear Grinder Works on the Generating Principle

Machine includes self contained drive and a 30 inch wheel with plane grinding surface. Handy location of control levers is feature. Three important conditions fulfilled to insure perfect involute generation. Work spindle rotates through a sleeve to which the power is applied.

**I**N the grinding of gears after hardening three different requirements have to be met: (1) The face of the tooth must be ground smooth; (2) the face must be ground to true involute form, and (3) the machine must index accurately so that the teeth will be properly spaced.

A gear grinder designed to meet these requirements has been brought out by the Lees-Bradner Co., and a photographic view of it is shown herewith. With this machine it is possible to grind spur gears with involute teeth of from  $14\frac{1}{2}$  to 24 deg. pressure angle, from 12 to 3 diametral pitch and from 2 to 12 in. pitch diameter. A grinding wheel of 30 in. diameter with a plane grinding surface is used. The wheel is supported on a stationary column and the work is traversed past the wheel by a slide having a reciprocating action. The work is given a rotary together with a correct sliding motion, in order to obtain the desired profile. To obtain this combined sliding and rolling action a segment corresponding to the pitch diameter of the gear to be ground is used, in conjunction with tapes or bands.

A diamond is used to true the face of the wheel. It is both lever and screw-controlled, and, of course, travels in a straight line to keep the plane face of the wheel true; it is used in conjunction with the wheel spindle micrometer feed.

The drive to the wheel is by an endless belt, self-contained on the machine. This belt is guided by two idler pulleys which are carried in a bracket, with sliding adjustment on the back of the column, to suit any diameter of gear being ground. A single belt is used to drive the machine from a line shaft, but a motor drive may be substituted.

Indexing is by means of hardened and ground plates, secured to the work spindle and completely shielded inside a case. The indexing is automatic and takes place at one end of the slide reciprocation. Setting the wheel at the proper angle is accomplished by means of a worm and segment on the swivel head. A pump circulates the coolant. The work can be held between centers, or supported on a mandrel having a taper shank to fit the spindle and supported at the outer end by the tailstock

## Meets Generating Conditions

To grind an involute tooth profile correctly with the above type of machine, it is necessary that the gear blank and grinding wheel have perfect coaxing motion of generation. Such accurate generating motion is hard to obtain. Three important conditions must be fulfilled in order that a perfect involute may be generated: First, there must be uniform motion between the tool and blank;

Figs. 1 and 2—End and side view of Lees-Bradner No. 10 gear tooth grinder

Fig. 3—Diagram of the mechanism for producing the combined rotary and sliding motion for gear generation. Fig. 4—Method of mounting bracket adjustably on column and securing tapes to tape bar. Fig. 5—Section through work spindle showing method of driving work arbor, construction of talstock and work mounted on arbor (gear pinion). Fig. 6—Section through grinding wheel spindle. Note the driving pulley in the center, the method of mounting the wheel on left, and worm and wheel micrometer adjustment for grinding wheel at right. Fig. 7—Micrometer adjustment for grinding wheel, used in dressing wheel and for setting for rough and finish cut

second, centering the tool and blank must be eliminated, and, third, there must be continuity of action between the tool and the gear tooth profile. A disk or segment and a tape are probably the most accurate method of obtaining a correct rotating and sliding connection. The use of tapes and segments is old, but in the past the power has been applied to the work slide as reciprocating action, and this reciprocating action converted into rotary motion of the work spindle by the tapes. In this gear grinder the power is applied to a sleeve through which the work spindle rotates when indexing. When the machine is grinding, the sleeve and work spindle rotate together as one unit.

The sleeve *A* (Fig. 3) carries the segment *B* to which one end of each of the tapes *C C* is fastened. The other ends are fastened to a bracket *D* on the column; accordingly, when the sleeve is rotated first in one direction and then in the other, the tapes will wind on and unwind from the segment, and thus through their pulling action on the bracket cause the work slide *E* to reciprocate. It is apparent from the diagram that there is a uniform torque load to the work spindle by a worm and wheel whose primary function is to rotate the sleeve in reversed directions; also, that there is uniform load on the tapes due to the fact that the frictional resistance of the work slide on the ways is maintained constant by gravity only.

#### Plane Surface Grinding Wheel

The problem of centering the tool and blank is done away with by the fact that a grinding wheel with a plane surface is used when generating. The tapes are anchored to the tape bar which carries the four tapes, two from each end. The bracket is supported and adjusted on the column for different pitch diameters of gears to be ground. These tapes are known as butcher saw steel, and are made of the finest Swedish stock  $1\frac{1}{4}$  in. wide by .025 in. thick. They are all of the same length and are placed in position loosely both on the tape bar and segment, and at the time of tightening up there is an independent end adjustment of the tape bar which is used to move the tapes endwise and in this way turn the segment from its vertical position for the original set-up. To find this position there is a zero mark on the bearing and the sleeve.

The drive for the wheel is from the pulley at the base, then over idlers in the sliding bracket to the grinding wheel spindle and up the stationary pulley at the top of the column. The main pulley shaft drives the gearing in the reverse feed box shown at the right hand end of machine. Speed change gears are used for the number of strokes per minute required of the work slide. The length of travel of the slide is regulated by a trip dog located inside the small circular door at the top of the gear case.

The starting and stopping lever for slide travel is shown at the right hand end of the work slide. This is also operated from the front of the machine. The wheel spindle is mounted on a combination of ball and bronze plain bearings to steady the action with oil films. End thrust is taken by a raised shoulder on the spindle close to the wheel, which shoulder is interposed between two ball bearings, and these are adjusted by the cap screws on the outer side of the flanged end cap.

The diamond of the wheel dresser is mounted in a ball socket container which can be swivelled to any angle, thereby using the diamond face on all its edges. This container is locked in the arm which can be fed either by worm and wheel or by hand, so that either a fast spiral cut, or a slow continuous cut, may be taken on the wheel face. This dresser is carried by the main swivel head

casting, locating the diamond point always in one plane, which is the generating plane, and the adjustment is made endwise of the wheel to the diamond when taking a dressing cut.

#### Changes Over Old Model

The machine here illustrated embodies a number of changes over the original design, including the self contained drive, a 30 in. instead of a 24 in. wheel, the use of four tapes in place of two, and a relocation of control levers for greater handiness.

The operation of the machine is as follows: A segment equal to the pitch diameter of the gear to be ground is located on the work spindle. The grinding wheel is set at the pressure angle of the tooth to be ground. The head carrying the wheel is raised to the correct height so that the wheel will cover the working depth of the tooth. The wheel is dressed with the aid of the micrometer adjustment, and is then moved to the starting position by the micrometer handwheel. There are two positive stop pins located in a circular T slot and these are used in conjunction with a positive stop to locate the wheel in a start and finish position. There is also an intermediate spring stop for the roughing cut. The starting stop is usually set to grind 0.004 in. from the tooth.

The gear to be ground is then locked on the work arbor with a tooth in contact with the grinding wheel face. The machine is started up and the roughing cut is taken, located by the spring stop, usually cutting 0.003 in. from the teeth once around. Then the micrometer is fed up 0.001 in. more to the finish stop, thus making up the 0.004 in. allowed for grinding. This brings the wheel back again into the generating plane and the same position in which it was dressed. When the wheel needs to be dressed again, which is usually every other gear, 0.004 in. is taken off the face. This is accomplished by an independent feed to the micrometer so that the stops for starting and finishing do not have to be disturbed.

This consists of a notched disk and a lever pawl. Releasing this pawl allows the wheel to be fed up 0.002 in. for each notch, so that usually two notches are used to bring the wheel against the diamond the average cut of 0.004 in.

The indexing of a gear is a very important factor in obtaining quiet running gears. The index plates are hardened and ground and are made from masters made by the Warner & Swasey Co. They are said to be very accurate.

#### Running Loads for Anti-Friction Bearings

TESTS bearing on the maximum running loads of ball and roller bearings have been conducted at the National Physical Laboratory recently. The machine on which they were made was kept running at 1300-1500 r.p.m. It seems that at this speed the ball bearings made by a well-known manufacturer will not fail until the shaft which it supports is dangerously loaded. It has not been found possible so far to damage a roller bearing to any serious extent. The tests show that ball and roller bearings properly mounted and protected from moisture or dirt are efficient under high loads, and it is possible that the ordinary running loads adopted are smaller than necessary. One interesting observation that has been made upon several different makes of both ball and roller bearings is that a few hours' running at the nominal maximum loading reduced the friction observed on subsequent running at lower loads. This reduction amounts to 10 or 15 per cent. Whether this is always the case or not we have not sufficient evidence at present.

# The Production of Pressed Steel Wheels Is Successfully Accomplished

This article describes the various operations required in fabricating one type of disk wheel. By proper heat treatment and knowledge of possibilities satisfactory results are being obtained. Great care required to prevent internal strains being set up in the metal.

By J. Edward Schipper

**T**HE constantly increasing use of pressed steel for automotive parts has resulted in some notable achievements in die work and in the use of this material. It would probably not be going too far to say that this is one of the most marked tendencies in automotive design, not only for automobiles, but for trucks and tractors as well. Recent achievements in the cold drawing of metal have far exceeded things that men who are old in the business believed possible. By the correct designing of dies and the proper selection and treating of the materials, some extraordinary results are being obtained.

The problem of using pressed steel for structural parts is not as simple as would appear on the surface. Great care must be used to avoid internal strains in the metal, thus making it impractical or even dangerous to use the finished products. By proper heat treating, however, and by an exact knowledge of what can and cannot be done in drawing the material, results are now being obtained which are satisfactory to many who have been very cautious about using this material heretofore for certain highly stressed parts.

The Gier pressed steel wheel, which is manufactured by the Motor Wheel Corp., offers a good illustration of the use of a pressed steel part in making a highly essential unit of automotive construction. This wheel, which is now being manufactured in quantity, is stamped out from  $\frac{1}{8}$ -in. steel sheet. By proper sectioning of the wheel, sufficient lateral strength has been obtained and an increase in resilience has been secured. This particular wheel has some special features which are of interest. It is so manufactured and designed that it can replace the wood wheel without changing the hub. It has been made interchangeable with the wood wheel by using the wood wheel hub without change and by employing aluminum spacer pieces so that the same width hub is secured and the same bearing mountings employed. In replacing the wood wheel with this stamped wheel, it is therefore possible to simply

remove the wood wheel and to slip the Tuarc wheel on in its place.

Another feature is the forming of the wheel in such a way that the same type of demountable rim employed on the wood wheel can be used on the steel wheel. Thus the installation is brought about with a demountable rim instead of a demountable wheel. It is claimed that this results in a reduction of total weight and an increase in convenience in tire changing since it is not necessary to lift the entire steel wheel.

Another feature of interest in the wheel is that a particular dish shape, employed for lateral stiffness, also permits the valve stem to pass through the dish, giving an accessible valve.

To incorporate these features in a stamped wheel and at the same time to secure the proper stiffness and strength gives a manufacturing problem of particular interest at this time when a very close study is being made of the possibility of pressed steel parts.

The main operation, that of drawing the disk is divided into three parts. The steel stock is, of course, provided in sheet form. The first operations are to secure the circular blanks. The steel sheets are pickled and sheared into squares and a

center hole for location is drilled. Locating from this hole, the circular blank is cut by means of a rotary shear, leaving an excess of material in the periphery to take care of the drawing operation.

## Making Operations Simple

The first drawing operation on the blank disk is performed on a No. 268  $\frac{1}{4}$  Toledo toggle press with a capacity of 410 tons. The operation, which is shown in Fig. 1, partially forms the disk. In this illustration the circular blank and the form of the disk after the first pressing operation are shown.

The same press equipment is used for the second drawing operation on the disk. This increases the depth of the draw and puts the disk into condition for its final

Sectional view through Tuarc wheel showing construction. The hub is a forging, the spacer an aluminum casting and the other main parts are steel stampings

Fig. 1—For this operation on a blank disk a 268½ Toledo toggle press with a capacity of 410 tons is used. Fig. 2—The same press equipment is used for this operation as in the first. Fig. 3—Forming and flattening disk. For this operation a No. 80½ Bliss press is used. The capacity of this press is 1091 tons. In this operation the disk is given its final shape, after which it is ready for center draw, punching for rim bolts, air valve stem hole and driving lugs. Fig. 4—When piercing rim bolts in the disk the bolt is extended through the felloe band and is held in place by demountable clips. The design on the bolt is such that when the nut is tightened on the clamping ring the bolt is drawn in place and forms a component part of the felloe band itself.

forming, which is done in the third operation shown in Fig. 3. This finish forms and flattens the disk. For this operation a No. 80½ Bliss press is used. The capacity of this press is 1091 tons. In this operation the disk is given its final shape, after which it is ready for the machining operation. The heavy press not only puts the final form on the dish in the wheel, but also is a truing operation to bring the wheel to the proper flatness.

After the final pressing operation on the disk, the center opening through the wheel is punched and drawn. The original small center hole which was used for locating the trimming of the circular blank is used to center the punched hole. The operations on the wheel after this center hole is punched and the center draw has been made, are simple machining operations which do not offer any complications. The flash is trimmed off the wheel in a

Fig. 5—For the first operation on clamping ring a 78½ Bliss press with a capacity of 453 tons is used. The blank for this operation is a plain hoop of steel. Fig. 6—Clamping ring in three stages. The one on the left is the ring blank; in the center it is shown after the first forming operation, and at the right after the final operation and piercing for rim bolts. Fig. 7—A truing operation on a 10-in. Collier-Smith beader. This brings the clamping ring to its final form and brings the ends together. Fig. 8—Assembling, inspection and paint booth. After assembly, the wheels are tested accurately for trueness; after which they pass to the painting booth. Note the compressed air nut tightener and the bolt clipping machine at the assembly bench

rotary trimming machine and the rim bolt holes are pierced. In some of the wheels for certain types of rims, it is necessary to depress the rim bolt holes and this operation is taken care of on the special machine illustrated in Fig. 4.

The rim bolt is extended through the felloe band and held in place by a demountable clip. The design of the bolt is such that when the nut is tightened on the clamping ring, the bolt is drawn in place and forms a component part of the felloe band itself. The machine shown herewith is a simple toggle punch, the same machine being used for depressing where necessary and for punching the rectangular rim bolt holes. There is also a driving lug hole, valve stem hole and side valve stem hole, all of which are pierced in the disk before it is ready for assembly. The drawing for the hub, which is known as the center draw, and the piercing of the hub bolt holes, are done in one operation.

Compared with the disk, the hub flange operation is simple. The hub flange is formed and pierced in one operation. The operations on the clamping rings, how-

ever, are a little more complex. This ring is also made from sheet steel stock which is first pickled, then sheared into strips and formed into hoop shapes. The hoop-shaped blanks are passed to a No. 78½ Bliss press, having a capacity of 453 tons. This performs the first forming operation on the steel hoop. A second forming operation is performed in the same press, which is illustrated in Fig. 5.

The various phases of the clamping ring are shown in Fig. 6. In the background of this illustration are the steel sheets which are the raw material for the work. The hoop to the left is the result of the first rolling operation after the sheets have been cut in strips. In the center is the ring as it appears when flanged over in the first stamping operation and to the right is the finished clamping ring which has been formed, then bored, pierced and washed to make it ready for assembly.

The ring does not leave the second drawing operation in exactly its final form, as there is a truing operation on a 10-in. Collier-Smith beader illustrated in Fig. 7 which brings the clamping ring to its exact final form and

brings the ends together so as to provide the correct roundness.

The spacing piece which is used between the inner and outer hub flange plate is an aluminum casting which is drilled in a Natco six-spindle drill which also drills the corresponding holes in the hub flange. Beside the drilling operation on this spacer piece, the only machining operations which it requires are boring and facing of both sides.

The assembly of the wheel is carried on progressively. At the present time there are seven men in the assembly line, each with his own operation to perform. The capacity of this seven-man line is not as yet known, as a complete production schedule is only in process of formation. The operations in the assembly are simple and consist of first mounting the spacer inside hub and outside hub on the disk by means of a drift pin and one bolt. Two men take care of this primary assembly passing the wheels to the third man, who inserts the other bolt in the flange. The fourth man has an air-driven socket wrench which tightens

the nuts up to a certain tension, after which they are hand tightened for final tension.

The wheel is then passed to an inspector, who mounts it upon centers and checks the wheel with the indicating point of an amplifier gage resting against the disk. This test is made for roundness of the wheels and must check within .055 in. The variations as the wheels come through the inspection gage, however, do not show, as a rule, above .025 in. After this inspection, the wheels are passed back to the bench where the bolt ends are clipped off on a shearing machine and then, by means of a pneumatic hammer with the same operator, the ends of the bolts are peened over. The wheels are now ready for the priming coat of paint, which is given them in a spray booth immediately adjacent to the assembly line. In fact, the last man on the assembly line who handles the air hammer lifts the wheel from the assembly bench and places it upon the spindle in the spraying booth. A portion of the assembly line showing the inspection is illustrated in Fig. 8.

## Some Newly Developed Electrical Equipment

**M**ENTION has already been made in the news columns of the fact that the Robert Bosch Magneto Co., Inc., will put on the market a line of ignition and other electrical and automotive devices.

Various improvements in design and construction have been made in Robert Bosch magnetos in recent years, mainly with a view of extending the range of operating ability and to make the machines absolutely dustproof and waterproof. The higher range of operating speeds is required by modern engines of the multiple-cylinder type which can be run in some instances at speeds beyond 3000 r.p.m., while others can be throttled down to exceedingly low speeds. On the new models there are absolutely no live parts exposed. The low-tension cable, instead of being connected to a binding post mounted on the interrupter cover, is led into the interrupter housing through a substantially horizontal hole in the molded cover, and the high-tension cables are also connected in such a way that all live parts are fully protected.

The magnetos are made for four-, six- and eight-cylinder engines, in the standard size and also in a larger size for extra large engines. A novelty is a miniature magneto designed for use on cycle motors and motors for scooters. This machine weighs complete only 2¼ lb. Being designed for use on single-cylinder engines, there is only one cable connection—the high-tension connection to the spark plug. No low-tension connection for a switch is provided, as the operation of the magneto is stopped by shifting the interrupter lever to a point beyond the working range.

Another new product is a combined magneto and generator specially designed for use on motorcycles. This is probably the most compact combination of this type that has ever been developed, a new principle being made use of in the construction of the magnetic field. The generator is of the standard cylindrical four-pole type and its field frame is made part of the magnetic circuit of the magneto. There are two flat magnets which form the magnet poles, while the cylindrical field frame forms the central part of the magneto field structure. Thus the magneto armature lies close to the generator field ring, and the whole structure is exceedingly compact. At the same time the problem of magnetically insulating the magneto field from the generator has

been eliminated. The generator of the combination has an output of 30 watts and is wound for 6 volts. Its voltage control is such that it can be used without a battery floating on the line.

An impulse starter which requires only a small turning moment to operate and cuts out at a low speed has also been developed.

A spotlight of neat and substantial construction is also being shown by the company. This comes with an integral switch and a universal bracket so that it can be aimed in any direction. Another new product is a double diaphragm vibrator horn. Of the two diaphragms of this device one has a relatively low and the other a high rate of vibration, which combination is claimed to insure both wide carrying range and absence of undue harshness. The horn is much more powerful than the average vibrator horn, and it is said to draw much less heavily on the battery than motor horns, for the reason that inertia effects are reduced to a minimum.

A new spark plug of the spearable type has recently been developed by the Robert Bosch Co. As will be seen from sectional view herewith, the insulator is held in the gland nut, which has its lower flange spun inward. Copper gaskets are provided on the shoulders of the insulator. When the plug is taken apart the gland nut, insulator and central terminal come out together. The insulator is not then absolutely rigid in the gland, but it cannot come out. A gas-tight joint is assured by the lower edge of the gland nut pressing against a conical surface of the outer shell. This is a ground joint and is claimed to be absolutely gas-tight. The central terminal screws into the insulator and consists of a steel outer end and a non-oxidizing inner end. In this new plug there are two electrodes in the outer shell, instead of three, as in the one-piece plug, these electrodes having arc-shaped ends. The plug is deeply recessed and therefore should not readily foul, but should a conducting layer of carbon form on the inner, exposed end of the insulator, the plug can easily be taken apart and cleaned in the usual manner.

# Most Factories Give Trucks Test Before Marketing

Manufacturers replying to questionnaire of AUTOMOTIVE INDUSTRIES agree almost unanimously that dealers should not be required to sell trucks unless the cars have proven their efficiency. Methods applied vary to some extent but in most cases a road test under capacity load is used.

A GENERAL opinion seems to exist among manufacturers of motor trucks that their product should be given a thorough test before it is shipped to a dealer. Results of a survey made recently by AUTOMOTIVE INDUSTRIES showed that most manufacturers hold that not only the public, but the salesman handling an article, is entitled to be assured that it can meet the tests claimed for it in sales talk and advertising literature. Just to what extent these tests should be carried out was a question on which some manufacturers disagreed, although approximately 80 per cent of the factory heads who replied were of the opinion that runs of about 50 miles with a capacity load should be made before a truck is allowed to be sold.

The following questions were embodied in the questionnaire sent to the manufacturers:

- Do you test trucks?
- Should they be tested?
- Do you test under load?
- Each part?

Is the expense of testing charged against the sales or manufacturing department?

A tabulation of the replies to the questionnaire shows the following figures:

- Do you test trucks? Yes, 41; no, 2; blank, 4.
- Under load? Yes, 40; no, 2; blank, 6.
- Each part? Yes, 5; no, 0; blank, 42.
- Expense charged to manufacturing? Yes, 12; no, 0; blank, 35.

From these figures it will be seen that of 47 replies received to this set of questions there were but two manufacturers who said their firms did not conduct tests before allowing trucks to leave the factory. It was interesting to note that the chief engineer of one of these concerns recommended that tests be conducted under load in order to bring out minor defects that might be overlooked in construction and which could easily be remedied if discovered in time. A typical opinion is expressed in the following quotation from one of the replies:

"Concerns which have a due respect for their output will not fail to make satisfactory weight tests before the trucks are turned over to the sales department. Just how a truck can be considered adequately tested before these load tests we do not see."

## Small Defects Important

Many defects can be brought out in a road test of from 50 to 100 miles. While these defects might not seriously hinder the efficiency of the product, they are apt to create an unfavorable impression with the purchaser. As one engineer expressed it, "Even a squeak or a rattle would undoubtedly cast an adverse reflection on a new vehicle." On the other hand, a defect such as would

probably not be noticed by the man who buys a truck might exist. To all outward appearances the machine might be in perfect condition, yet a skilled mechanic who drives it for 50 miles could easily discern that trouble and adjust it satisfactorily at small expense and perhaps save the purchaser considerable time, money and wrath by so doing.

There were seven manufacturers who did not specifically state that their trucks are tested under a load. One replied that a capacity load was not used in all cases. The chief engineer of this concern, however, declared enough of a load was used to discover any lack of power, imperfect springs or defects in transmitting mechanism. One concern tests its trucks with a load 50 per cent greater in weight than the rated capacity.

## Separate Part Tests

Testing each part separately apparently is not a general practice among manufacturers, as but five specifically stated that this operation was carried out. The others, however, did not say definitely that each part was not tested, and the conclusion might be drawn that, while such concerns do not deem it necessary to give all individual parts a separate test, the more important ones are pretty thoroughly examined before they are allowed to become a part of the whole. One company analyzes all raw materials it receives, and, as the parts are manufactured, they are carefully inspected and tested and, when assembled, the truck is given a thorough road test. An official of this company expressed the opinion that "any company which does less is not building their product with as much care as they should."

Another concern that does not test trucks under a load declared this was omitted because of the thorough tests each part is given before it is put into the machine.

The expense of testing trucks generally seems to be borne by the manufacturing department, rather than the sales organization. While there were but twelve specific answers to this last question, all of these said the cost was included as a part of the expense of production. The other companies indicated that the tests were made at the factory and did not indicate that the sales department had any connection with them.

The opinion prevails that it is the duty of the department producing an article to turn it over to the company's salesman or dealer in such condition that there can be no question as to its efficiency. "We do not expect our dealers or Sales Department to have any expense incurred by them," wrote the president of one concern, "but consider it the duty of the Manufacturing Department to deliver the trucks in perfect condition."

One factory has put into effect a system whereby the expense of testing their trucks, under full weight, is

borne by the factory, but should any defects arise within a week or so after it is sold, the expense of correcting these defects should fall within the budget of the dealer.

"We believe," this official wrote, "that the first 200 miles of the truck's life is the most crucial period, inasmuch as there is a greater tendency for things to become worn in and to become loose when the truck is new and seeing its first service. After the truck has run this distance, however, and is again readjusted and everything is made tight, it is ready to go to work.

"We urge upon our dealers that whenever they sell a truck, a certain amount of profit be set aside for this checking up, which should be made after the truck has been driven a week or two. We feel that this expense should be borne by the dealer who sells the truck and should be considered as a part of his selling expense."

Another point mentioned in favor of the manufacturer conducting the tests was the inability of the Sales

Department to properly and economically test a truck.

"So many different troubles arise, due to the inability or inexperience of the sales organization to test the truck, that it does not seem advisable for any sales organization to put any truck to a test unless taken up directly with the Engineering Department of this company."

On the whole, there seems to be little variance in the methods and kinds of tests performed before finished trucks reach the public. Of course, different factories have different systems. It is doubtful, however, if a uniform system of testing could be established, if, indeed, there was any demand for such a system. The product of each factory has individual characteristics, all of which are not contained in trucks made by other companies. Tests that would apply to one truck might not apply to another, and the engineers of various factories have certain ideas in mind when they specify certain tests to be applied.

## Argentine Show Stimulation to Trade

THE enthusiasm with which the automobile, as a universal means of transportation has been received by the Argentine Republic during the past ten years is tersely indicated when a comparison is had in the number of automobiles in daily use at the present time, 75,000, with the number of vehicles employed in 1911, approximately 10,000.

Perhaps there is no country in all Latin-America where the use of the automobile as a real necessity in everyday life has been so generally adopted as in Argentina. Immense areas covered by the farms and ranches out of reach of the railways cause the automobile to be a practical necessity for rapid communication between distant points not served by rail facilities.

The universal demand for automobiles has met with a ready response on the part of Buenos Aires importers, who, for generations past have been accustomed to anticipate the demands of the country and seek to supply the same from foreign sources. So decidedly is this the case that at the present time there are approximately 150 automobile importers established in the city of Buenos Aires alone.

Some four years ago the Touring Club Argentine undertook the inauguration of an annual automobile show, which met with most marked success. This initiative has subsequently been followed up during the months of October and November of each year. The expositions are held in the "Pabellón de las Rosas" situated on Avenida Alvear, near the Palermo Park, the city's most fashionable thoroughfare. The shows have at all times met with the decided support of all automobile, truck and tractor importers and the daily attendance at the show has been made up not only by residents in Buenos Aires, but also by crowds of visitors from all interior points.

It has been impossible to obtain statistics regarding the number of sales effected at these shows. However many sales are closed by the throngs of salesmen attending the various exhibits and without doubt many prospective purchasers, while not placing an order during the exhibition, are nevertheless strongly influenced toward this end by the opportunity of comparing under one roof the merits of the many cars exhibited. From the importer's point of view these shows are also very productive in securing new agency connections for distributing centers, since practically all automobile dealers in Argentina make efforts to visit the exposition. Naturally it is well to bear in mind that the foregoing statements have to do with those expositions held during the past four years

when the general business situation in Argentina was exceptionally good and it is therefore difficult to express an opinion as regards the merchandising possibilities of the forthcoming show to be held next November.

Plans for the next Annual Show during the latter half of November are now being rapidly whipped into shape and even though this show may not be held on a scale commensurate with former expositions, there is no doubt but that the larger and more responsible importers of automobiles, trucks and tractors will place on exhibit their products as in previous years. The possibility exists, of course, that a number of the smaller importers will not take part in the exposition due to their desire for exercising the strictest possible economy in their efforts to tide over the present period of hard times. Moreover, those automobile men who are close observers of the buying psychology of the Argentine people are inclined to be exceedingly pessimistic, knowing as they do the tendency of Argentines to over-spend in times of prosperity and to under-spend when the slightest signs of business depression appear on the horizon.

However this may be, the value of the show in stimulating trade is as well recognized by Argentine dealers in automotive products as it is by their confreres in the United States, and it will be taken advantage of by all of those live manufacturers and dealers who realize the potential possibilities of this market, and, are willing, even at the cost of considerable outlay in time and money, to cultivate this field in the hopes of obtaining a firm foothold here against the time when business has again become brisk.

**A** CAST-IRON research association has been organized in Great Britain and it is hoped that by intensive research the iron foundries may regain some of the trade they have lost in recent years to the drop forging, steel pressing and die casting industries.

In no other country in the world, it is said, has the cast iron industry been more encroached upon in this way than in Great Britain. The malleable cast iron section has suffered particularly. Of the 3000 foundries in the country, 170 produce malleable cast iron. Whereas Great Britain was at one time the largest producer in the world of malleable cast iron, its output to-day is only 66,000 tons per annum, as compared with 1,500,000 tons in America. The average output in Great Britain is but 8 tons per week per foundry, whereas in America it is 100 tons on the same basis.

# America's Power Resources

The power resources of this country are the very basis of our national and industrial greatness, hence a knowledge regarding them should be possessed by every citizen, and especially by manufacturers and engineers. Waste in their recovery and uses aggregates billions of dollars annually, a fact which makes it vastly important to study the subject.

**P**ROBABLY no natural resource is of such great importance to this country as that of power derivable from coal, oil, gas and water, yet the public, including manufacturers, engineers and others whose business it is to utilize these resources is, on the whole, poorly informed if not totally ignorant regarding the status of these resources and their relation to our economic system.

To illustrate this fact, it may be well to point out that if this country were in the midst of great business and industrial activity, it would be facing this winter a severe coal shortage such as that which caused the closing of many plants in the winter of 1917-18. Yet there are few who appreciated the reason for that condition or are aware that it seems certain to recur; much less have steps been taken to prevent its recurrence. Shortage of rail transportation is by no means the only factor in the situation. It is inherent in our outworn system of energy distribution.

This and many other facts of equal or greater significance are set forth in the book by Chester C. Gilbert and Joseph E. Pogue entitled "America's Power Resources."

This volume should, we feel, be studied by every manufacturer and engineer, not as a matter of academic interest but because without the knowledge and perspective given by a study of this kind, it is impossible to grasp the full meaning of the present fuel and power situation, and without such understanding the necessary concerted action among fuel producers, distributors and users which alone can solve the situation, cannot be brought about. The defects of the situation, now temporarily mitigated by the current industrial depression, will if allowed to continue bring about in time an intolerable condition, with serious consequences to the entire industrial fabric of the country.

While the book deals with a more or less technical subject, it is by no means technical in character. While it is written for the layman, it will prove equally interesting to the engineer, and for a book of its kind is unusually readable.

In this review we quote extensively from important portions of the text, supplying only such connecting passages as seem necessary. It need hardly be said that one must read the book in order to secure a complete and thorough understanding of the subject.

The introductory chapter deals with human labor and mechanical work and shows how the development of social consciousness and rising wages have made necessary the increased use of and efficiency in mechanical means for multiplying production. Chapter II, on the foundations of industrialism, shows that

Modern civilization is dependent upon the accomplishment of more work than human labor is capable of performing. This multiplication of human effort is brought about through the utilization of the energy stored up in natural resources—coal, oil, gas and water-power.

The United States possesses the most extensive energy resources of any nation in the world, producing annually three-quarters of a billion tons of coal, one-half billion barrels of petroleum, 700 billion cu. ft. of natural gas, and ten million horsepower of hydro-electricity. We supply nearly one-half the world's coal and over two-thirds of its oil.

It would require the labor of three billion hard-working slaves to accomplish the work done annually in the United States by our energy resources. The use of energy materials gives to each man, woman and child in this country the equivalent of thirty servants. Our type of civilization arises from this organized use of animated energy.

But our energy resources themselves and the means for handling the materials from which they are realized have been left to a haphazard development without plan or order. Furthermore, in bringing into use the materials from which power is developed we have sacrificed a high percentage of these valuable materials. For example:

For every ton of coal produced, our methods of mining have placed a second ton beyond recovery; for every thousand feet of natural gas turned out, a similar quantity has escaped; and for every barrel of petroleum that has seen useful service, several barrels have been wasted. These losses are inherent in the excessively competitive methods of production followed in this country and have caused no great concern, as it has been generally felt that the unmined supplies of the materials were so vast that distant generations alone would feel the loss. Recent inventories of the unused portions of these resources, however, go to show that such is not the case—that our best and most convenient coals will be depleted in a few decades, that approximately half of our petroleum is already used up, and over half of our natural gas is gone.

In addition the mere bulk of energy materials that must be handled has become so great that a critical problem in transportation is created. Coal alone constitutes more than one-third of the freight hauled by our railroads.

Industrialism has outgrown our present inefficient manner of handling the energy contained in coal and rapid changes are due to come as the system is found increasingly incompetent to sustain the forward march of industrial growth.

Beyond this our current utilization of energy materials is for the most part inefficient in the extreme, and the four sources of energy supply have been exploited as competitors, the cheapest and most convenient one being drawn upon.

Thus the limited reserve of oil is being used in place of coal and waterpower; coal is doing its own duty and that of waterpower as well; natural gas, the ideal fuel for homes, is in large part devoted to the crudest of industrial applications; waterpower is largely neglected. For the sake of expediency, our most precious assets are being squandered at an unbelievable rate. The very abundance of supplies has made it unnecessary to take thought or care in their behalf.

We now face a transportation system incapable of accommodating industrial expansion and the requisite growth in coal production at the same time; an oil production which has reached its maximum; a natural-gas output that is on the decline; a water-power development that is stagnant. Yet the demand for an increased energy supply is not to be gainsaid. There can be but one way out—a change in the development of the resources which will give a higher percentage of energy service from the materials brought into use.

The issue has a twofold aspect. Under present methods of dissociated, bulk production, we can neither secure an adequate supply of energy to meet the needs of the immediate future nor hold the price of energy down to levels at which it can be used to fulfill its proper functions. Without an abundant supply of energy we cannot have industrial progress; without a cheap supply social progress cannot be maintained.

The time is rapidly arriving when organized society will take stock in a scientific manner of the drift of affairs and by means of the forces at its command direct its destinies to a favorable consummation. The energy resources lie so concretely at the bottom of human welfare that their cultivation cannot wisely be neglected.

In the third chapter the authors deal with coal which they term the basis of national welfare. It is shown that

Coal is more than accumulated energy; it is a storehouse of valuable chemical products as well, awaiting merely proper treatment to yield valuable commodities with no sacrifice of its energy content. A striking commentary on the undeveloped status of coal is the fact that nearly all of the coal consumed in the world is burned in the raw state, with utter disregard of the products of potential value thereby destroyed. Smoke is the ever-present evidence of this loss.

The nature of coal is outlined and the three principal kinds are defined, while a few paragraphs are devoted to its origin and geological formation. Coal formations underlie nearly a half million square miles of the United States and are widely distributed throughout the country, though the bulk of it comes from comparatively few regions. The character and relative importance of various fields is pointed out. Our coal resources are so vast that less than half of one per cent has been used to date, but estimates as to how long our coal supply will last are beside the point, as the coal mined today is the best in the country. Before long, perhaps within fifty years, much of our high-rank coal will be exhausted.

The practical question, then, is not how long in an absolute sense our coal will last, but when shall we have to make changes in our industrial structure because the conveniently located and high-grade coals, upon which concentrations of industry and specialized uses are dependent, are beginning to run short? That time is closer at hand than is generally realized and is a consideration which demands the fullest utilization of the remaining supplies.

Considerable space is devoted to the important matter of coal mining.

While the early mining of anthracite was very wasteful, marked improvement in engineering practice has taken place with the development of the industry. The mining of anthracite as to efficiency is now in sharp contrast to the conditions under which most of the bituminous coal is still produced.

It is shown that there is great difference between the methods followed in mining anthracite and bituminous coal.

A striking feature of bituminous mining is the lack of developed methods of storage, because of the tendency of the product to crumble and even take fire, which requires a steady flow of coal-cars past the mine mouth so long as the mine is operating. A shortage of coal-cars, in consequence, means a stoppage of coal-mining.

The production of coal in the United States is so wasteful, not only of coal itself, but of labor and capital as well, as to raise the question whether the status of coal-mining is adapted to the conditions under which coal occurs and the needs which coal must meet.

The country's most basic resource is produced through the medium of a thousand disintegrated units, working without concert and under conditions of destructive competition.

Bituminous coal-mining as an industry is beset by conditions which are the occasion of present wastefulness and the justification of apprehension for the future. Scattered and unorganized, most of the individual companies are small and financially weak; inadequate co-operation in engineering practice exists; new technical developments are slow of growth; coal is mined for the most part by obsolescent, long-established methods.

With no means of storage developed, the average mine can produce coal only when railway cars stand ready to receive it; a fluctuating demand, accentuated by seasonal variations, leads to

instability of operations; many mines must close down in slack months, with destructive effect upon the conditions and supply of labor. The supply of labor also is not equal to the capacity of the developed mines; hence a labor shortage always develops in periods of prosperity, when the demand for coal suddenly increases. For years until recently the price of coal at the mine ranged from \$1 to \$1.15 a ton, a figure so low that only the best and most easily obtainable coal could be extracted by the cheapest methods of mining, irrespective of the waste involved; the tonnage of thin-seam and high-cost areas sacrificed in the process amounts to more than half the total coal produced to date. Many districts have been burdened with a leasing system that obligated the company to remove a given tonnage each year, irrespective of market demand or price, with the result that the richest portions were drawn from seam after seam with irretrievable loss to present needs. The fixing of wages on the basis of thick and easily worked seams has imposed severe penalties upon inferior conditions, precluding the introduction of new and improved methods. Added to this, the policy of the Government, as exemplified in its anti-trust laws, has forbidden combinations and restrained co-oper-

### Do You Know

**T**HAT our power resources stand at the very basis of our economic and industrial system?

That many economic difficulties are directly traceable to failure to understand the importance of these resources and to use them intelligently and economically?

That one-third of the country's freight is coal?

That unless conditions are changed, we are certain to experience in times of great industrial activity a coal shortage similar to that which occurred in the winter of 1917-18?

That industrialism has outgrown our present inefficient methods of handling energy contained in coal?

That our petroleum resources are already one-half exhausted and the remainder being consumed with reckless waste?

That three-quarters of the gas produced in this country is natural gas, nearly half of which is wasted with an annual loss of nearly a quarter billion of dollars?

### If Not

and if you would understand the meaning and importance of these and many related facts regarding our fuel resources and their bearing upon our modern civilization,

### You Should Read

the accompanying article and the book upon which it is based.

ation, with the result that large-scale, standardized operations, a paramount and distinctive American achievement, are virtually lacking in the mining of coal.

The trouble with coal-mining is too much competition, resulting in a lack of balance between production, transportation, and distribution. Coal-bearing land is so abundant in the United States that an excessive number of mines have been developed. The productive capacity of the coal industry, in consequence, is far in excess of the requirements of the country. In addition, the demand for coal varies so from summer to winter that for the past thirty years the average working year has been only 215 days in length, leaving 93 possible working days when the mines were idle.

The coal industry is unstable, speculative, and unreliable alike to producer and consumer. The crying need is for stabilization. With proper operation, an excess mine capacity of some 150,000,000 to 200,000,000 tons and an excess labor force of some 150,000 men could be eliminated.

These conditions are particularly undesirable because they concern a product of fundamental importance. In efficiency of production, the coal industry is not to be compared with the other great basic industries, such as the iron industry or the copper industry. The difference is to be attributed to the competitive system of small-unit mining, which has prevailed in this country and indeed been perpetuated against a natural tendency otherwise, by a public policy hostile to combination.

The foregoing facts must be borne in mind in order to understand the need for so reorganizing our coal industry as a public utility rather than along the lines of unrestricted competition. The present system encourages great waste, for competition makes it profitable to mine only the richer portions of deposits, leaving much valuable coal unworked. The advantages of co-operative mining are realized in other countries and should be brought about here.

The great difficulties in the way of adequate distribution of coal by rail will, it is thought, result in the establishment of great power stations in the coal fields and the transmission of the electrical energy there generated to industrial districts where the power is consumed. Congress has authorized a "Superpower Survey" with a view to developing a unified system of electric transmission lines in the eastern industrial zone. This involves the recovery of commodity values in the coal as by-products, a phase of the coal industry which holds great possibilities but which is in its infancy in this country.

Present utilization of coal, therefore, involves a very low recovery of the energy content and an almost total loss of the commodity values present. This, of course, necessitates the production, transportation, and distribution of a much larger quantity than would otherwise be required; concentrates the whole cost, in respect to the consumer, upon the modicum of energy extracted; requires the imports of materials which might be manufactured from the non-energy components; holds back the development of latent possibilities in coal products; besmears with dirt and smoke an untold wealth in civic improvements.

Heretofore the need for a coal by-products industry was not generally appreciated, inasmuch as there was plenty of fuel; transportation difficulties had not loomed up; coal products could be purchased from Germany; nitrate could be imported from Chile; and, in general, the whole matter of coal was taken for granted.

The need for progress in this direction is very great, as will be seen from the following:

Our present annual coal output could be made to more than double its service, or—accepting the current service requirement as a standard—that less than half the output can do the present work and in addition make heavy contributions to the supply of fertilizers, motor fuel, and chemical products. The total loss, on the basis of this estimate, runs well above a billion dollars a year, or over ten dollars for each inhabitant of the United States. Of such measure is the average man's pecuniary interest in the full utilization of coal.

The industrial progress of this country has been sustained by the mining of an ever increasing quantity of coal, until the very bulk of the total has become a critical weakness in this country's industrial life.

As Herbert Hoover has remarked, the coal industry is "the worst functioning industry in the country." For adequate social and industrial advance, this industry should stand at the head of our basic industries, not at the foot.

### Oil, the Accelerator of Progress

Petroleum, the sole source of gasoline, is of immense importance to the automotive industry, hence peculiar interest attaches to Chapter IV dealing with this subject. The magnitude of this energy resource has made possible practically all automotive development.

But since petroleum deposits of the United States have been drawn upon with extraordinary rapidity and the supplies have already suffered serious depletion, the matter of their approaching exhaustion assumes the light of immediate importance. The comforting assertion that such considerations may be safely left to future generations does not apply to petroleum.

The nature, characteristics, geological occurrence and location of fields is concisely covered, and particulars showing the degree of exhaustion of various fields are given. See Fig. 1. The petroleum industry is, it appears, far better organized than the coal industry, but is not co-ordinated throughout.

Considerable space is given to various methods used in the recovery of petroleum from the earth, and particular stress is laid upon the waste brought about by the competitive system of well drilling which puts a premium upon the use of wasteful methods. From 30 to 90 per cent of the oil is left underground, and it is probable that on the average less than 25 per cent of the oil underground reaches the pipe-lines. Some of this waste is unavoidable or inherent in present methods of recovery, but a modernization of laws governing petroleum mining, which now, in effect, are quite largely responsible for the situation, would alleviate at least one great evil.

The system of pipe-lines used to transport petroleum to refineries near the centers of population, the refineries themselves, their methods and system of distribution, are interestingly described. A brief historical outline of the application of petroleum products to commercial and other uses leads to the conclusion that

The prospective demand for motor fuel is so great that it is probable that eventually all the petroleum products now burned as ordinary fuel will be used in internal-combustion engines.

### Concerning Natural Gas

The fifth chapter deals with the important subject of natural gas, its occurrence, characteristics, value, distribution and use. Many automotive manufacturers have made large use of this resource, but the failing supply has already forced the substitution of artificial gas, and is likely to do so in increasing measure in the future. Some industries have been forced to migrate on this account.

The waste which occurs in the exploitation of natural gas reserves and in the use of this valuable fuel is scarcely believable:

The history of the natural-gas industry of the United States "is an appalling record of incredible waste." The annual reports of the Conservation Committee of the Natural Gas Association of America "are stinging indictments of a criminal system, fostered by both the gas companies and the public, that has resulted in wasting more gas than has ever been utilized." Samuel S. Wyer of the Fuel Administration estimated in 1918 that the annual wastage of natural gas in the United States was equal to the current consumption—that is, 800,000,000,000 cubic feet. At 30 cents a thousand cubic feet this an-

nual loss would be appraised at \$240,000,000. The contemplation of such figures is staggering to the imagination.

The waste of natural gas does not concern future generations; these losses are being paid for to-day. In no direction is conservation more critically needed, nor more promising of such immediate returns, as in the realm of natural gas. In a few short months in 1918, the Bureau of Oil Conservation of the Fuel Administration effected economies which resulted in the saving of millions of dollars' worth of this valuable fuel, but with the coming of peace this valuable work, undertaken as a war measure, was terminated.

The cause of this waste and means for checking it are detailed, but cannot be outlined in this review.

### Water Power, an Unused Annuity

Chapter VI, bearing the above title, makes it clear that

Despite the fact that electricity has been in common and growing use in this country for many years, it has effected virtually no change in the basic conventions of coal distribution, and has led to the development of a small fraction merely of the available water-power.

The water-power of the United States, converted to electrical energy, is capable of turning every industrial wheel and illuminating every street and building in the entire country. And, the resource is country-wide in distribution.

The present production of hydroelectricity in the United States represents roughly the equivalent of 55,000,000 tons of coal, whereas nearly 400,000,000 tons of coal go into the production of steam-power and carboelectric power.

Of course, the whole default may be attributed to the Government's lack of action, but the result of ill-advised legislation, while significant, has been exaggerated.

It must not be forgotten that coal and oil have been so bountiful in this country that only the cream of the deposits has been exploited; a project contemplating the development of a water-power site faces competition with such a situation. Our fuels have been mined on such an extravagantly uneconomical basis of opportunism that a superabundance of coal and oil has been maintained on the market.

Fuel resources are fixed in quantity and are in the nature of capital which does not draw interest; waterpower, on the other hand, may be compared to an annuity, the annual increments of which lapse if not currently used. Hence, as a concession to convenience and in the flush of resource wealth, this country has run into the economic impropriety of drawing upon its energy capital while neglectful of its energy annuity.

Commonly as much as a fourth of the coal-fired power employed in centers of population has its energy applied in the form of electricity. Yet, with the rarest exceptions, this energy is transported to the centers of use in the form of coal and there the electricity is generated in steam-power plants. Electric-power usage has merely been appended to the established structure of steam-power practice, with the result that the employment of power has been greatly facilitated, to the further aggravation of the broad problem of transportation. So far the very force that has the capacity to correct the transportation evil has merely served to accentuate it. By virtue of electricity more power is consumed, more raw materials are required, more goods are produced, more coal is freighted.

Particulars concerning the various influences which hold back the development of water power make interesting reading, but space limitations prevent their inclusion here.

Chapter VII is devoted to a consideration of smokeless

fuel, the supply of anthracite and bituminous coal, coke, gas, etc., and the relation which they bear to industry and the need for heat in the home.

About two-thirds of the coal consumed in the United States goes into the production of power which is divided almost equally between the industries and the transportation systems; about one-sixth is used as a raw material for making substances employed industrially, such as metallurgical coke, upon which the iron industry depends, and gas, nitrogen compounds, benzol, tar, and coal-tar products. One-sixth approximately is employed for heating homes and other buildings. It will be observed, then, that the combined industrial requirements outweigh the needs of the home five to one.

It is shown in Chapters VIII and IX that our whole industrial system is dependent upon an adequate supply of power, and that

Transportation is the throat of industry, through which all of its materials enter and emerge. Upon the size and flexibility of this opening depends the rate at which industry can grow. From a broad point of view it would appear that the transportation problem cannot be adequately solved without due attention to the matter of power. Effectiveness of transportation involves three factors:

1. The employment of the equipment best suited to the task.
2. The advance elimination of superfluous weight.
3. The full utilization of the material transported.

The energy in coal is not concentrated before shipment, but is hauled in its substantial, bulky form; while the coal at its destination is not used so as to yield anywhere near its full service.

Energy is virtually the only natural resource product susceptible of concentration that is shipped broadcast in the crude condition. The dictates of demand, it is true, still call for a large proportion of the supply in the crude state, and

to this extent concentration in advance is obviously impracticable. But the order of requirement is changing rapidly, and even now over one-fourth of the call is for the concentrated product—electricity.

Not only are the railroads the chief haulers of energy in bulky form, but they likewise constitute the chief single consumer of this material energy which burdens their lines. The railways burn approximately a fourth of all the coal produced in this country, this item alone representing at least a tenth of their total operating expense.

It is commonly recognized that one of the weakest features in the industrial development of the United States is the over-accentuated responsibility falling upon the railways; any measure tending to lighten this weight obviously strikes at the roots of a fundamental and important issue. A plan for adequate inland transportation in this country is conceived to embrace: (a) airplane service for special mail and for passengers restricted in time; (b) motor-truck service for short-haul freight and in farming districts in co-ordination with parcel-post deliveries; (c) railway service for normal freight and passenger accommodations; (d) trunk-line, deep waterway haulage for slow-moving and bulky freight; and (e) transmission lines for the delivery of electrical energy from the coal-fields and water-power sites, in co-ordination with pipe-lines for the transmission of energy in gaseous form.

The coal applied to the production of power amounts to nearly half a billion tons, and is hauled chiefly by the railways to its multitudinous points of use, although in many instances as much as a quarter of the supply is there turned into electric power. This method of handling coal imposes a tremendous burden upon the railways, leading to congestion and shortages

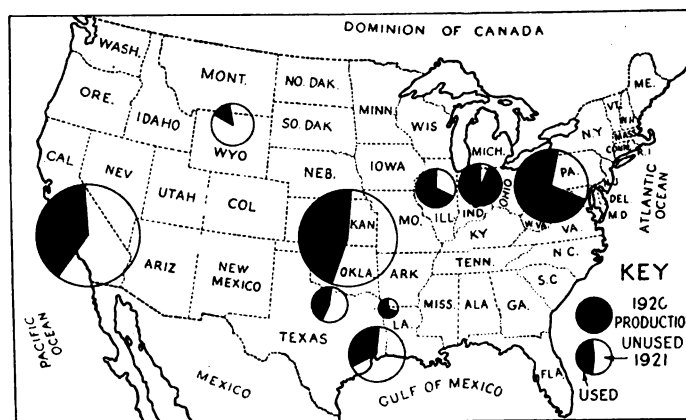

Fig. 1—The eclipse of petroleum. Map shows degree of exhaustion of principal oil fields in the United States

in periods of business prosperity when the demand for coal enlarges and the quantity of other materials demanding transportation at the same time increases. The use of fuel oil and crude petroleum for purposes of steam raising and the like, which is considerable and represents over half of the total consumption of petroleum and its products in point of bulk, sustains a gross overproduction of petroleum, and in consequence contributes markedly to a premature exhaustion of that resource, with initial effects already in sight.

### Fuel Demands of Automotive Transportation

The construction program of the automotive industry affords no prospect of let-up in the pressure of fuel requirements. On the contrary, the injection into the situation of a notable capacity for truck production introduces an element that bids fair to overshadow even the tremendous automobile demand, while the item of tractor manufacture looms ahead with a fuel significance scarcely second in importance. And the production of aircraft, with their high fuel consumption, is scarcely under way. If the drift of these matters be projected into the future unabated, it is evident that the supply of motor fuel will have to be doubled every few years. The automotive industry is young and vigorous, and its continued expansion will place an unexampled burden upon the motor fuel resources of the country.

Those who count upon the discovery of new oil deposits materially to affect the basic situation overlook the fact that already for ten years new discoveries have been failing to do so, notwithstanding the sensational aspects of new developments when viewed separately.

Compared with the large and rapidly increasing annual draft upon the petroleum reserve, the supply seems startlingly inadequate to sustain for any satisfactory period of time the motor-fuel situation as it now stands. Moreover, it is well known, because of greater drilling necessary, that petroleum may be mined only at increasing cost and with increasing difficulty as the resource is depleted. It is already a common belief among petroleum engineers, that the oil output of the United States has reached its maximum, and the end of the present era of flush production in Mexico is in sight.

A big fraction of the domestic petroleum is gone; whether that fraction is one-half, as present knowledge indicates, or is one-third or even one-fourth, makes no difference in the consideration demanded by the situation. The fact remains that the size of the fraction has meaning to people using petroleum to-day and therefore represents an economic factor that must be reckoned with now.

It is, of course, very evident that the present tendency cannot persist to the point of even approximate exhaustion, because conditions, naturally arising, such as price increase, growing imports, and others, will serve to relieve the tension and thus spread the remaining supply over a greater number of years. But of practical importance is the period of economic stress that is ushered in when the resource faces a greater demand than it can fill in the customary manner. That is a period of readjustments to meet the new conditions, and arrives far in advance of physical exhaustion.

In short, as the situation is shaping up, the demand for gasoline is increasing more rapidly than resources and means are being developed to provide this product. Accordingly, a gasoline shortage, accompanied by a rise in price, is a prospect to be anticipated, if no means for relief are brought into action. A marked rise in the price of motor fuel, if not compensated, will retard the development of the automotive industry and hold back the whole field of activities dependent upon its unbroken advancement.

It will soon be necessary to bring coal and hydroelectric power to the aid of a growing number of those activities now dependent upon oil fuel. Benzol and alcohol hold better promise as blending agents in connection with petroleum products than they do as single fuels; but the utmost that may be expected from them in the calculable future is that they will augment by a small percentage the total supply of motor fuel.

Significant additions to the motor-fuel supply from oil-shales are still a number of years distant, and the whole matter cuts little figure in the immediate problem, however large ultimate contributions may turn out to be; although such volatile shale oil distillates as may come on the market may be expected to

find their way into the motor-fuel supply in the form of composite fuels, in much the same fashion as benzol and alcohol.

The automotive industry, theoretically, can stop the change now taking place in fuel by holding fast to the present engine in detail, but this procedure will so limit the supply and increase the price of fuel that in practice the engine will have to give way. It is concluded, therefore, that an era is arriving when the engine will have to make rather radical concessions to fuel, as a relief to a strained situation; and the problem before the automotive industry is, first, to recognize this situation, and, secondly, to establish means for making these concessions with the maximum easement to the supply and price of fuel. Anything short of this will mean just so much of a detriment to the growth of automotive transportation.

The paramount problem, therefore, is to insure, so far as possible, a parallel and complementary development of fuel and engine. This attainment is dependent, in part, upon the degree to which the mutuality of interest as between the fuel-producing industries and the engine-building activities is recognized and turned to use as a motive for co-ordination; in part, upon the degree to which the Government interests itself.

There is need for a steady progress on the part of the engine toward greater thermal efficiency. The average automobile is notably wasteful in its use of fuel, and the fuel supply may see its service doubled without an increase in volume, once fuel economy becomes a paramount issue in engine design.

### Equalization of Industrial Opportunity

This subject is dealt with in Chapter X, and is a phase of industrial economics seldom given adequate consideration.

A co-ordinated and balanced development of the coal and water-power resources of the country will serve to equalize industrial opportunity and therefore to unify the economic interests of the country so that a constructive economic policy agreeable to all sections may win country-wide support. But in addition to its bearing upon national policy, a distribution of power advantages will make for an indirect but very significant gain in the matter of transportation; for industry may then strike a more perfect balance between the location of raw-material sources and markets.

The concluding chapter of the book deals with the subject of industrial evolution, and contains the following significant statements:

We are involved in a wasteful and careless exploitation of our energy resources, which is rushing upon us a premature depletion of our richest sources of supply and creating imminent problems in industrial readjustments of far-reaching significance. We have permitted, unchecked, the development of harmful concentrations of industrial activities in limited areas favored with fuel, to the creation and aggravation of labor problems that seem insolvable. We have seen our transportation system staggering beneath the sheer bulk of energy haulage, with a recent break-down in operation which clearly indicates the incapacity to function in periods of industrial expansion.

As a nation we have failed to sense that the inadequate development of our energy resources is responsible for a large measure of the social shortcomings that are present in our economic situation. The problem at bottom is one of education.

In short, we stand in need of a co-ordinated development of our energy resources to support a sound economic and equitable social advance. We need a system of production for our energy materials which will be in harmony with the geological occurrence of the resources, to eliminate the appalling waste of effort now taking place in their exploitation.

We need a new method of transportation for our bulkiest energy material, coal, which will be in keeping with our form value needs. The development of a common-carrier system of energy transmission lines will fill this want.

We need a revision in the methods of utilizing our energy materials, so as to insure a higher recovery of the energy content and a proper employment of the commodity values for the purpose of reducing the cost of energy. This result may be attained through a furtherance of the principle of multiple production, coupled with adequate attention to the efficiency of the appliances concerned in utilizing energy.

Unfortunately the Government, which should set the lead in this matter, has failed to sense its responsibility.

# Heavy Demand for Motor Equipment in Oriental Nations

Love of display creates market for lavish trappings, loud horns and shiny radiator decorations. Manufacturers of accessories find bigger field for goods in Far East than car makers. Business increasing.

**A** CENTURY rooted sense of the dramatic, a childish love of gawdy or refined display and an inherent craving for the ostentatious in addition to being predominant Oriental characteristics from "somewhere East of the Suez" to points north of the maritime province of Vladivostok are the underlying factors of the motor car accessories market of the Far East. To the Oriental every day is a different act in the whole play, his life, and every moment he feels the responsibility of being the star of the cast.

The same inner prompting which recently brought one of the ruling war lords of the nation of China to have made to his order by an American manufacturer an armored limousine, equipped with machine guns, armor plate, non-shatterable plate glass, and arm slings for body guards mounted on the running boards, governs the lesser lights of the Orient in buying electric horns, dome lights, and radiator ornaments. The same tendency makes limousines popular with the older generation and screaming sportsters the desire of the young.

To the manufacturer of accessories in the United States the Far East, to a great degree, presents a market that is in almost direct contradiction to that of the Western countries. In this section of the world those devices which find increasing favor as "owner driver" accessories are a drug on the market. The element of cheap labor gives to the owner of even the lowest priced car in the Orient the ability to employ a chauffeur. More often there is also a footman. It is a safe estimate to say that 90 per cent of the motor cars in the Far East are chauffeur-driven. The motor car owner in the Far East in the majority of cases knows little and cares less about his car, his chauffeur's knowledge is confined to tinkering with the spark plugs and electrical connections, and if anything goes wrong the car goes to a garage where foreign experts are employed.

The firm belief on the part of the Oriental chauffeur that the majority of trouble in the working parts of the car can be traced to the spark plugs has created a market for these which is comparatively out of proportion to that existing in Western countries. This market is also increased by a demand from the marine activities of the various Eastern ports for use in motor boats.

## "Squeeze" System Helps Market

Because of a lack of care lamp bulbs are also replaced with a frequency unparalleled by any Western country. Often, too, such breaks are not alone due to a lack of care but to a system which has grown up in connection with the motor car industry of the Far East which is the bane of the owner and the delight of the chauffeur.

This system is called in China "squeeze." In the United States it would be a commission. No matter in what business or occupation, the Oriental is always on the outlook for "squeeze." The garage owners, for the most part, have to pay a few cents commission on gasoline, more on

motor repairs and on everything that is done, to the chauffeur. This helps the spark plug market, as the chauffeurs soon learn to unload them. This also increases the sale of tires, lamps, and often moving parts of the engine and car.

Radiator decorations of the most lavish type find a ready sale in the Far East. On the whole the American manufacturer has *not* grasped this idea and has attempted to sell cheap pseudo comical figures when nickel plated, bronze and silver plated decorations of more classical design would have met with immediate favor.

## Electrical Equipment Popular

Electric fittings of every description, step, dome, inside corner and other types of lights with fancy coverings in imitation of cut glass find a ready sale. Dash lights, in fact, lights of any description located any place on the car can be disposed of easily.

The Oriental love of display and personal advertisement finds solace and contentment in electric horns—the larger and louder the better. Hand horns are also fairly popular. The native is a slow moving individual as a pedestrian and it adds considerable to the enjoyment of a spin in a motor to be able to give these people a shock by means of a loud and deep voiced horn.

In China and India the rapidly increasing body building industry is giving rise to new markets for manufacturers of fittings and parts. These markets demand the highest grades of upholstery materials, beadings, window tassels and carpets. In the average native limousine these must all match with a high degree of exactness. Price is no object with the native buyer.

## Most Cars Locally Built

While not within the realm of accessories proper, the styles of cars used will give an idea of the market generally. In the Far East closed cars predominate. For the most part they are locally built because the buyer and owner can have his own whims embodied in the making and also because with native labor these closed bodies can be produced in the Orient cheaper than they can be imported from the United States.

While the motor car business has suffered a slump generally throughout the Far East during the past year, the prospects for the future are taken in all sections to indicate a revival of former activities and constantly increasing business.

**A** DEMONSTRATION of the Case, Fordson, Glasgow, International and Titan tractors was recently held at Haifa, and with the Case tractor at Beersheba. As a result, endeavors are being made on the part of a few landowners in the Beersheba district to combine for the purpose of purchasing a tractor, and it is hoped that others will follow this example.

# The FORUM

## Front Wheel Wobble

Editor, AUTOMOTIVE INDUSTRIES:

Somewhat over a year ago the writer contributed an article to AUTOMOTIVE INDUSTRIES in which some of the causes of front wheel wobble were analyzed. He knew then (and stated) that the subject was treated incompletely and asked for suggestions as to other possible causes.

One such has recently been brought to his attention by Eric Wahlberg, chief engineer Nash Motors Co., the explanation of which was overlooked in the original discussion. It is very readily explained by diagram herewith.

Suppose the front axle be tilted so that the centerline of the king pin strikes the road either in front of or behind the point of contact of the tire with the road. Then if a side force is applied to the tire at the point of road contact, this will have a moment about the king pin axis the amount thereof depending upon the distance AB. On the other hand, the motion of the car will offer an opposing moment directly that the wheel is turned from the straight position, if the king pin is in the same plane as the wheel. With the conventional design of axle there will be a trailing or castering action at all times that the car is in motion because, both the front wheels being outside the king pins, they tend to spread apart in front.

Now the gyroscopic action of the wheel even at low speeds is quite considerable, which means that to deflect it sideways suddenly will require a fair effort. Once deflected the movement of deflection will continue until a sufficient opposing moment is encountered and hence a pendulum wobbling of high frequency can easily be started.

This it is, in bad cases of wobbling, that causes the whole front end of the car to shudder, without any perceptible vertical oscillation, an action that had greatly puzzled the writer and which in the original analysis he realized he could not then explain.

Diagram of front wheel with tilted axle

There are two positive cures for wobble. One is to use an axle with king pins set truly vertical; the other is to introduce sufficient friction to damp out the wobble or rather to "dead beat" it.

Wobble which develops in old cars can usually be cured by tightening up all the joints and connections in the steering. If it occurs in a new car it can usually be traced to excessive castering. If much caster is considered necessary the remaining alternative is to use king pin bearings with a fair amount of friction, not ball or roller bearings.

A. LUDLOW CLAYDEN.

## The Fuel Problem as a Carbureter Problem

Editor, AUTOMOTIVE INDUSTRIES:

While hundreds if not thousands of pages have been written on the fuel problem, I fail to remember any discussion of it on the basis of self-evident and indisputable facts. I want to quote from one letter received by me several days ago from the engineer of a prominent carbureter concern, and also from the circular of one still more prominent. These extracts prove beyond question that the carbureter as applied to-day is really looked on as a metering device.

If these devices were actually productive of fuel efficiency there would certainly be no true grounds for charging waste. This fact is indisputable. But, beyond any question, a lot of the precious liquid gets by without producing results. There is a reason:

A rather clear, if homely, example to show why it is difficult to get fuel economy lies in the fact, as I have several times roughly figured out, that in a truly efficient use of fuel one common teaspoonful should give from 200 to 250 power charges to the cylinders of a medium-sized, 6-cylinder motor. This, based on around 20 miles per gallon, which should be easily possible. To break up a spoonful of liquid into this number of parts means extreme divisibility, and if this is not accomplished, it, of course, means waste.

Now it is another self-evident fact that to get true economy you must trap this excess before it gets into the cylinder or even manifold and not afterward, which would be like locking the barn door after the horse is stolen. It simply means real evaporation or extreme divisibility, which is about the same thing. This is not accomplished to-day, hence the fuel problem.

There apparently exists a rather hazy idea of this matter of vaporizing. Natural evaporation is confused with boiling. The first requires surface, the latter temperature. It is simply a question of surface in relation to bulk. Without hesitation I will say that it is perfectly possible to design a carbureter which will give the required surface and at the same time not only vaporize the liquid fuel but give a homogeneous mixture to the manifold for distribution to any number of cylinders. Not only will efficiency but economy of operation result therefrom. My firm idea is that when there was a

marked decrease in the volatility of fuel, no means were taken from the carbureter side to improve on natural vaporization, but it was left to the engine builder to provide artificial means by boiling, or, as one prominent expert has said in a recent paper, cooking.

I do not believe that a vapor thus supplied can give equality of mixture that is truly efficient and economical.

GEORGE M. BROWN.

## Testing Aluminum Castings

Editor, AUTOMOTIVE INDUSTRIES:

I wish to indorse Mr. Ernest V. Pannell's article on "Testing Aluminum Castings" printed in your issue of Sept. 1. Mr. Pannell has very ably defended the American practice of casting test bars of aluminum alloys in green sand as against the permanent mold method recommended by Dr. Rosenhain in your issue of Aug. 4. It is readily agreed that of two methods capable of giving the same degree of uniformity, the one giving results more nearly comparable with the physical properties obtained in actual castings should be chosen. It is my intention to show that by proper standardization, test bars cast in green sand can be made to show a satisfactory degree of uniformity.

The Engineering Division of the Air Service has adopted a method of casting test bars in green sand, as shown by the accompanying photograph. The patterns, including the gates, are made up on a match plate, thus insuring uniformity of molding. The mold is slightly tilted so that in pouring the metal flows up-hill. The pouring head and riser are 1¼ in. in diameter and a 3-in. cope is used. The results given in the following table represent melts of the standard No. 12 aluminum alloy (8 per cent copper) made up in the McCook Field Foundry, during the period July, 1920 to July, 1921. These results have been grouped according to the copper-aluminum hardener used, since it is believed that much of the variation in results obtained in aluminum castings can be traced back to the hardener used in the preparation of the alloys.

629.....	20,890	2.5	54.0	12.3	2.84
Average	21,240	2.80	54.3	12.0	2.85

Test bars cast in green sand

<i>Cu-Al Hardener—Melt 821</i>					
895.....	22,260	1.50	58.0	13.3	2.85
<i>Grand Average</i>					
Tensile strength	.....	.....	.....	.....	21,300
Elongation	.....	.....	.....	.....	2.49
Brinell	.....	.....	.....	.....	55.4
Scleroscope	.....	.....	.....	.....	13.1
Specific gravity	.....	.....	.....	.....	2.86

The results given for each melt are the average of the three test bars cast as already indicated. The results from the three bars always agree very closely, except where there are obvious flaws, which reduce the strength of any one of the bars. For ordinary purposes, it is not necessary to cast three bars, two being sufficient, one to be used as a re-test in case the first bar shows a flaw. However, for experimental work, we have found it very desirable to cast the three bars in the same mold.

It is a well known fact that the physical properties obtained in an aluminum test bar depend to no small extent on the pouring temperature. In general, the lower the temperature, the higher the physical properties obtained. For this reason it is the practice in our foundry to pour the test bar mold just before pouring the casting, thus the test bar is poured at a slightly higher temperature than the casting, and, therefore, the results obtained are conservative.

Material Section,  
War Department Air Service.

## Better Vehicle Repair Methods

THE second edition of the Automobile Repairman's Helper is so greatly enlarged and so radically changed that it bears little resemblance to the first edition which was printed some two years ago. The contents consist of the Better Mechanics articles, which have been appearing in Motor World for the past four years, and these are edited and arranged in an orderly manner with a complete index so that any subject or any car or truck can be located very quickly. The book is the work of S. Thornton Williams and J. Howard Pile.

The articles were prepared with the thought of assisting motor car mechanics to better methods of care, repair and maintenance of motor vehicles and in the preparation of the material over 2000 shops have been visited in various parts of the country, factory service departments called upon for data and various methods of performing operations observed and studied.

The present edition, including practically all articles up to date, has become so large that it was necessary to divide it into two volumes. The first volume, now ready, takes up building design and layout, systems for saving time and money, shop equipment, standard shop practice on cylinders, electrical systems, batteries, bearings, etc.

Volume II, which is in preparation and will be printed shortly, takes up other problems of the repairshop and gives detailed shop operations on a number of other cars and component parts such as clutches and axles.

# Washington Unemployment Conference Deserves Attention

Fixed habits of work and non-flexibility of men in ability to do more than one job is one factor in the present situation. Tendency of the public is to charge industry with the responsibility for unemployment. Conclusions of conference will develop effect produced by this tendency.

By Harry Tipper

**T**HE opening of the President's conference upon unemployment is a reminder of the fact that we have an unemployment problem of considerable proportions, and that this problem assumes a public character because of these proportions and the impossibility of any single agency providing the alleviation from the attendant troubles.

As members of one of the largest industries, the automotive manufacturers should be very much interested in the deliberations of the conference at Washington and in the proposals emanating therefrom.

The character of the conference indicates the general belief that this problem is of such importance that it requires the consideration of every branch of opinion in the development of either temporary or permanent suggestions for its alleviation. The presence of the manufacturers, labor leaders and representatives of the general groups of the public means an admittance by the political bodies of the public interest in this matter and of the way in which the problem is affected by the industrial conditions of labor outlook.

This is the first time in the history of the United States that the unemployment situation has called for any public and political consideration. While there have been periods of considerable unemployment in the financial crises of the past, they have not been so widespread and they have not attracted the public consideration which has been demanded in connection with this one.

In the period up to the war the United States was possessed of a manufacturing capacity hardly equal to its requirements for domestic consumption. The excess in imports of manufactured articles over the exports of similar products was sufficient to show that the capacity did not quite reach the dimensions of the domestic consumption.

Since the war has ended the manufacturing capacity of the United States is, for the first time, larger than the immediate or probable requirements of the population, and, therefore, the unemployment question demands an attention not so visible at any period in the past.

The difficulty of maintaining continuous employment has grown with the subdivision of the industrial operations and the more rigid specialization in the occupational divisions.

Not so many years ago a machinist was a man who could turn his hand to the operation of any of the usual

machines in the metal trades or the manufacturing side. He was capable of making his own tools and fixtures and of adapting his machine to the production of various kinds of work. His skill, therefore, was fairly flexible and could be turned to a good many things in the course of a year's operation of the factory.

To-day most machinists are only operators of machines, capable of operating a limited range of machinery of the same kind and under similar conditions. Unless there is a sufficient volume of work in their own particular small occupational branch of the business, these men are unable to fill industrial requirements, and it is not unusual to see one department of a factory working overtime, while another department is on short hours.

The trade union development has added to the rigidity of this labor skill by organizing unions in different branches of the industry and defining the measure of skill which permits entry into such a union.

In some lines of industry these definitions have been carried so far that their interpretation has led to a series of functional strikes and many functional disputes arising out of a disagreement as to whether new operations belonged to one branch or the other branch involved in the particular industry. The building trade has been very prolific in these disputes, and some of them suggest the extent to which the definition of work has been carried by the standards of membership in the various organizations.

It is recalled that in building one of the important banks of Chicago, when the steel arrived for the building of the safety deposit boxes, the contractor was able to close the pavement on order from the city, and that he might not be delayed with this work he had the steel dropped to the basement by his regular rigging gang, so that the pavement above could be closed and the other work proceed. It appeared that this work was a part of the work of the safe-movers in one of their branches and they declared the regular riggers should not have been used for the purpose. Therefore, the safe-men called a strike on the building and refused to operate until the pavement was torn up, the steel removed from the basement to the sidewalk and put down in the regular way.

In a building in New York, several months ago, a new device was introduced for the purpose of improving the heating system. A question arose as to whether the erection of this part of the equipment belonged to the plumbers or to the steamfitters. The discussions of this point grew very acrimonious. Finally a strike was called because of this dispute and a month was lost before the question was settled.

These, of course, are extreme cases, but there is a general tendency—accompanying the continued subdivision of operations—to a greater rigidity of skill and a greater dislike for any change in the work which will call for adaptation of that skill to other operations.

This rigidity is primarily a psychological matter arising out of the fixed habits of work that become more difficult to change as they become concentrated upon fewer elements. It is enhanced by the organization of such men into groups and their attempt to define their own work for the purpose of developing standards of membership, apprenticeship and other matters.

The employment problem is very closely associated with this because the rigidity of skill and habit makes it more difficult to use the idle workers in any operations other than those to which their skill has been previously applied.

We are fortunate in this country in that a large part of our working population has not been trained in this specialized skill for more than one generation and retains as yet a measure of adaptability in connection with their work. Coming, as these workers do, from peasant classes and from farming occupations or from parts of the world where industry is not so highly specialized, they have been accustomed to turn their skill to a good many things, adapting themselves to each change of work. This capacity they have not entirely lost, and for that reason there has been a good deal of re-employment from the ranks of the unemployed, reducing the total problem in a measure and increasing the flexibility of the labor organization to that degree.

However, it should be noted that the industrial fabric can be maintained at such a perfect balance as to provide work for every worker at an equal pace in connection with the percentage of total production demanded by the market only when the manufacturing capacity is noticeably less than the market requirements and it is possible to employ all of the workers a reasonable proportion of the time. Considering the surplus manufacturing capacity possessed by the United States as a result of war activities, it is unlikely that we shall require all the labor in the same proportion for a number of years, so that the question of unemployment is likely to remain with us in some proportions, at least, over quite a period of time.

Whatever the manufacturer may think about the matter, or whatever may be the abstract viewpoint of the individual, this conference indicates that political authorities and practical business men believe the responsibility will be placed upon industry, the general population and the political governors in about equal proportions.

The reaction of the public indicates that, from the standpoint of the average citizen, industry must accept a considerable share of the responsibility for unemployment. Any political action in this direction, of course, will simply be in the way of taxing industry or forcing industry to do certain things because of political necessity.

In Great Britain and to a greater extent in other European countries the unemployment problem has required governments to control, subsidize or to engage upon industrial operations to an extent which would have been incomprehensible before the war.

In any case, industry must pay for the lack of employment directly in the industrial difficulties of small profits and slower turnover, while the consumer, of course, is charged with this addition to cost before the transaction is completed.

So long as the income of a proportion of the population is reduced materially by the uncertain character of its employment or the extent of its unemployment, the purchasing power of that portion of the population is diminished, the costs of industry are increased and the amount of product which can be secured is decreased.

Industry works at the best efficiency when everybody is sufficiently employed, but when there is no real shortage of product and no great competitive bidding for service. The balance of industrial employment is probably more effective at a normal product load than it is at any point above or below that. The purchasing power of the population is at its most stable point when industry is operating at normal load.

In a declining market, where every element of cost becomes important because the price cannot be adjusted to the cost, but the cost must be adjusted to the price, any inefficiency arising from partial load, unemployment and destruction of organization add automatically to the cost of the individual unit of production.

From these standpoints the manufacturer is primarily affected by the question of employment, and the methods of alleviating the present unemployment problem should have his careful attention. They may be only suggestions at the present time, without any binding force and with no particular weight, but they will affect public opinion to some extent, suggest further analysis to some of the interested observers, and the conclusions may return to embarrass the manufacturer later if their significance is missed and their tendency lost sight of when they are reached in the present conferences.

The unemployment problem has reached the consideration of the politicians and the public in a definite way for the first time in the history of the United States, although many suggestions have been made in this direction previously. That fact should warrant the manufacturer in considering the conclusions arrived at by the conference and in considering the effect which such conclusions may have upon his own outlook.

There is a general tendency, undoubtedly, to charge industry with a measure of the responsibility for unemployment and for its solution. Irrespective of its justice, this tendency shows some indications of growth, and the conference will develop in its conclusions the effect produced by such considerations in the deliberations of that body.

THE new number of the *International Labour Review*, the monthly magazine issued by the International Labour Office of the League of Nations, contains figures showing the huge development of trade unionism since 1913, 1919 and 1920 were 16,152,000, 42,040,000 and 48,029,000 respectively.

Of the total of 42,040,000 members in 1919, 34,061,000, or 80 per cent, belonged to European countries. Of the remaining 7,979,000 non-European members, 5,985,000 belonged to the North American Continent. Trade union membership is very marked in the United Kingdom, Germany, the United States, Russia, France and Italy, which accounted in 1919 for no fewer than 33½ million members, while the other 24 countries accounted for only 8¾ millions.

The four great industrial countries—the United Kingdom, Germany, the United States and France—included between them more than 28 million members, or 66 per cent of the recorded world total of trade union membership in 1919.

## Winter Repair Work

THE news columns of AUTOMOTIVE INDUSTRIES last week told of a movement started by Automotive Service Associations of New York and Brooklyn to avert the usual slump in winter automobile repair work. Their campaign includes spending \$16,000 in newspaper and folder advertising to urge the car owner to have his automobile overhauled during the winter months instead of putting it off until early spring when repair shops are rushed with orders.

To the manufacturer of automobiles who has service stations established in various cities throughout the country this campaign offers a suggestion. Whether or not combined action among the various repair men of the different cities was taken, individual effort could accomplish much. The advantages of such a plan are apparent. Not only would the service station be made a paying proposition during the winter months, but the car owner would also derive benefits in that there would not be the long wait for his car in the spring while other machines were being overhauled. The work would be done at the

time he uses his car the least and the repair man would be busy the year round.

This system, if put into effect, would not likely result in decreased business during the spring, for enough work will come in to keep the shop running at full speed. During the spring the service man can take care of only so much business and he often has to turn away many prospective customers. If it were possible for him to persuade his regular customers to bring in their cars during the months between November and March he would find that his shop would be filled with new customers when the spring rush started.

While primarily the move was started in an association there would be nothing to prevent the individual service man to launch a similar campaign among car owners in his territory.

## Progressive Car Development

IN commenting upon the handicap which the present status of the used car market places upon the sale of new cars a prominent engineer, who is also an executive holding a high position in the industry, recently said that the best if not the only way to overcome this handicap, so far as it affects the near future, is to build new cars which are so far superior to used cars now available that no user will have one of the latter type. To which the immediate rejoinder is, can it be done?

It not only can but it will be done, not, of course, by the conservative sit-tighter who changes nothing until the other fellow shows him that he can't live unless he improves his product, but by the progressive who has vision—who analyzes the shortcomings of that which is, and sets an ideal for the performance of the future product toward which he continually strives.

What, then, is this new car to accomplish which the present-day car fails to do? Primarily, it must be more efficient, not only in respect to fuel consumption—though this is of great importance—but in all factors which enter into the cost of operation. It must return more for each dollar spent upon it. It must be more dependable—freer from difficulties which demand attention by the user and by service departments. It must be accessible and easier to repair when repairs must be made. It must be more comfortable to ride in. It must handle as well as or better than the best we have to-day. This is not all, but it's enough to make food for thought, for experiment. It calls for but little information not now available—simply the intelligent use or combination of facts we already know.

Some people who have given the matter careful study believe that the car which will do 75 miles on a gallon of fuel is in sight. Experimental cars which have done this or but slightly less are already in existence. It is not too much to expect that performance in other respects will undergo a similar radical improvement. Much remains to be done in experimental development before improvements of this character are incorporated in the commercial product, but the manufacturer who is not following work

of this kind and not seeking to do his share in research upon which sound development is based is certain to suffer when he awakens to discover that his product is out of date and in no position to compete with that of more progressive contemporaries.

## Power Resources and Their Conservation

WHEN a person stops to analyze the importance which power resources play in our modern economic system it is not difficult to see why our own country has become the greatest of all industrial nations. It is largely because of our endowment in coal, oil, natural gas and water power that we have achieved this greatness in competition with nations less well supplied with energy resources. There is danger, however, that we will fall into the habit of regarding our fuel resources as inexhaustible; whereas half of our petroleum reserve has already been used, the best of our coal deposits are becoming depleted, and our supplies of natural gas are failing rapidly. In the face of this situation we permit to continue an appalling and largely preventable waste in all our fuel recovery operations, and much the same can be said regarding the utilization of the fuel ultimately recovered.

No revolution in this regard can be worked in a day, but much can ultimately be done by education and by intelligent legislation. The automotive industry is a great consumer of fuel and is responsible for the production of equipment which uses a large percentage of refined petroleum. The intelligent conservation and economical use of our fuel resources is therefore a matter which we cannot safely neglect if we would serve our own best interests.

It is easy to be indifferent—to say that the whole fuel problem will work itself out in time, but indifference is a costly luxury when it concerns so important a matter as fuel, and those who indulge in it must expect ultimately to pay the bill. The wisdom of starting now to study and help work out a solution of the problem cannot be questioned. Read the article in this regard which appears on another page of this issue. We predict that you will find it worth while, to say the least.

## Building Dealer Efficiency

THE schedule of topics announced for the N. A. C. C. members meeting which begins to-day indicates the probability of real progress in connection with an important phase of marketing—that of dealer relationships. Two out of the three topics announced for the general meeting have to do with this subject while the third is directly related to an important dealer problem.

The importance of satisfactory dealer relationships has been strongly emphasized by the experience of recent months, and a careful study of the problems involved is likely to be worth all the time and effort expended in this way. Merchandising costs throughout all industries have increased during recent years

in far greater proportion than have production costs. In fact, the latter have constantly decreased while the former have constantly increased. The efficiency with which the dealer organization functions in relation to the manufacturer has a strong bearing on these costs.

The facts are fully recognized by the majority of manufacturers, and definite progress is being made in many instances. The entire problem, however, is rather complex and a more fundamental analysis of the various factors is still necessary.

## Increasing Punch Press Production

THE advances made during recent years in the production of pressed metal and stamped parts renders the punch press of constantly growing importance in production operations. There is, however, one definite objection to this machine. It is extremely dangerous to operate under ordinary conditions.

In many punch press operations it is necessary for the operator to place his hands between the jaws of the press twice. In a brief talk before the automotive section of the National Safety Council, A. L. Kaems of the Simmons company emphasized this danger in a striking manner. He put it in this way: "We have devised all kinds of safety devices, such as two-hand trips, push-buttons, gate-sweeps and others that have prevented many accidents, but just the same way as the railroad companies make us cross their tracks, so are we making our employees place their hands underneath the ram of the press twice every operation. Suppose a man does 1000 pieces per hour. That would mean his hand would be in the danger zone 2000 times per hour. In 8 hours it would mean 16,000 times and in 300 days 4,800,000 times. . . . You will agree that when a person is compelled to flirt with danger 5,000,000 times per year and is not injured he is just lucky."

The great production usefulness of the punch press renders specially necessary a more careful study of safety methods in connection with it. The difficulty with most of the safeguards devised has been that they tend to decrease the speed of production. Since most punch press operators are working at piece-work rates, this fact has, of course, led them to disregard or to render ineffective the safety devices. Where the operators were on a day-rate basis the management has been loathe to install such devices because of the decreased rate of production involved.

As pointed out by Mr. Kaems, however, a little careful study of individual operations will enable the manufacturer to find means of pushing or sliding the work into the die in 90 per cent of the cases. Some months ago AUTOMOTIVE INDUSTRIES described in detail how this has been accomplished at the Simmons plant. The idea is entirely practical and is comparatively inexpensive. The danger of injury to the operator is eliminated and the production of the machine is materially increased in practically every case. A more careful study of safety methods for this important machine will increase production and reduce costs.

# Peerless Negotiations Consummated

## Active Management Assumed by Collins

Approximately \$4,500,000 Involved—Initial Payment 20% With Rest in Serial Notes

CLEVELAND, Oct. 3—Richard H. Collins, who recently resigned as vice-president and director of the General Motors Corp. and president and general manager of the Cadillac Motor Car Co., through the purchase of a substantial block of stock today assumed the active management of the Peerless Motor Car Co., it is announced by Roland T. Meacham, investment broker, through whom the negotiations were closed. Approximately \$4,500,000 is involved in the deal.

### New Directors Chosen

At a meeting of the directors of the Peerless Truck and Motor Co. immediately following the signing of the contract, Collins was elected president and general manager of the company. Resigning directors included B. G. Tremaine, F. S. Terry, Lewis Kittredge, Theodore Frech, Geo. Y. York and Harrison Williams. These were succeeded by R. H. Collins, Wilbur H. Collins, C. E. Sullivan, F. A. Trester, F. J. Miller and A. C. Earhart. The following directors remained on the board; H. A. Tremaine, Roland T. Meacham, Walter C. Baker, W. H. Staring and Geo. B. Siddal.

The deal is the result of negotiations which had been under way for several months and definitely sets at rest reports that Collins would only become a stockholder in the company without assuming active management. Under the terms of the agreement signed to-day, Collins agrees to purchase from B. G. Tremaine and his associates, who have virtually been in control of the Peerless company, a minimum of 50,000 and a maximum of 80,000 shares for \$50 a share.

### Meacham Makes Statement

The initial payment will amount to at least 20 per cent and the rest will take the form of serial notes bearing 6 per cent interest and secured as collateral by the stock purchased. The fact that Collins expects to come here at once to live and assume active control of the company indicates to the financial district that he soon will be in the saddle in preparation for the 1922 season.

In making the announcement, Meacham said:

"I think this is the biggest thing that has happened to Cleveland industry in the last five years. Collins has long admired the Peerless principles of engineering, and has reached the conviction, after an intimate study of Peerless design and construction, that the line thoroughly embodies the quality ideals which have been his inspiration during his entire career.

"It has also been known to his intimates for a long time that Collins has had a high regard for the city of Cleveland, its people, its industries, its way of doing business and its future.

"With characteristic promptness, he has already formulated definite plans for the expansion of the Peerless business. Details of these plans will be announced from time to time."

### All Time to Plant

Collins stated that he would give his entire time and attention to the big Peerless plant in Cleveland and that the company would continue to manufacture eight-cylinder motor cars.

"I am a firm believer in the principle," he said, "that the director or general manager of a big business like the Peerless Company is only a trustee, who must at all times be mindful of the interests of the four groups that make for the success of any enterprise, the stockholders, because they furnish the capital to carry on the business; the men who make the product, because they give it its intrinsic value; the men who sell it, because the success of the manufacturer depends on the success of the merchants who put the product in the hands of the public and the men who buy it, because after all, a large body of satisfied owners is the greatest asset that any business can possess and this satisfaction results solely from the policy of giving the customer a full dollar's worth of value."

### Collins Versatile

Collins is considered one of the most versatile men in the motor car industry. While much of his effort has been along merchandising lines, he has a knowledge of manufacturing second only to his knowledge of selling cars. He went to the utmost pains to gain his intimate knowledge of manufacturing because he has always held that only by knowing what was going on in the factory could he most intelligently interpret his product to the buyers outside.

As absolute dictator of the policies of the Cadillac Motor Car Co. he doubled the company's yearly sales revenue, opened a branch house in Chicago, whose business expanded so quickly that within less than a year it was necessary to double the floor space of the buildings; planned and finished in Detroit a new sales and service building and designed and erected a new Cadillac factory that is said to be the world's most modern automobile plant.

When Collins' resignation from the Cadillac Motor Car Co. was accepted a few months ago, it was pointed out as a

(Continued on page 695)

## Merger Is Completed By Steel Companies

New Corporation Has Outstanding 300,000 No Par Common and \$10,000,000 Preferred

MASSILLON, OHIO Oct. 3—Steel mill properties with combined assets in excess of \$20,000,000 have been brought together in the merger just completed of the Central Steel Co., the National Pressed Steel Co. and the Massillon Rolling mill Co., all of Massillon.

The new corporation takes the name of the Central Steel Co. and the following officers have been elected: Chairman of the board of directors and president, R. E. Bebb; first vice-president, F. J. Griffiths; second vice-president, C. C. Chase; third vice-president, H. M. Naugle; secretary and treasurer, C. E. Stuart.

The reorganized company has outstanding 300,000 shares of no par common stock and \$10,000,000 of preferred stock. The merger of the three companies brings the Central Steel Co. into prominent position among the steel producing corporations of the country with complete modern equipment and facilities for producing all kinds of commercial alloy steels, hot and cold rolled sheets, hot rolled strip steel and light structural steel sections in a combined annual output of 450,000 to 475,000 tons of finished material.

Several new buildings and new machinery were recently added to this property, most of which was put in operation last March. The plant as it is operating produces approximately 50,000 tons of sheet products annually and the arrangement is such that an increase of 50 per cent in production can be achieved without additional buildings or power equipment. The Massillon rolling mill plant was designed and functions especially as a producer of sheets for the automotive industry.

## Irish Fordson Plant Increases Its Output

LONDON, Sept. 5 (By Mail)—After spending \$3,250,000 on the Fordson tractor enterprise at Cork, south Ireland, which was started in war time with the marked good-will and help of the local people, and amid much grumbling by interested parties on this side, it looked recently as if the enterprise was doomed to an inglorious end. Production fell off and the number of hands diminished to a few score. Trade has revived, however, and the works are increasing production, with nearly 1000 employed.

# Earl Motors, Inc., Succeeds Briscoe

## Car Will Also Bear Name of Executive

### Arrangements Are Made Through Chicago Bankers for \$5,000,000 Additional Capital

JACKSON, MICH., Oct. 3—The Briscoe Motor Corp. and the Briscoe car will be supplanted in the automotive field by Earl Motors, Inc., and the Earl car, both the company and the car being named for Clarence A. Earl, former vice-president of Willys-Overland, who became president of Briscoe in March last. Five million dollars in additional capital will be put into the business, arrangements for handling the finances having been perfected by Earl with Chicago bankers during September.

In announcing the reorganization, Earl said the Briscoe directors had voted unanimously for the introduction of the new capital, necessitated through the fact that the distribution end of the business had been expanded by the addition of 20 new distributors and 240 dealers in the past six months, both the new financing and the new policies will come before the stockholders' meeting of Oct. 20 for final ratification.

Enclosed models of the Earl car, which will reflect a general improvement in the former Briscoe line, will be ready for delivery Oct. 15. Open models will be ready Nov. 1. For the present Briscoe cars are being produced, though most divisions of the factory are busy on producing parts for the new car.

### Discusses Outlook

Discussing the outlook for business, Earl said:

"The action our board of directors has taken is really our first step toward expansion to meet a demand which we are certain will develop by the first of next year. The minimum capacity of our plants today is 15,000 cars annually. With general business conditions pointing to a strong revival of activity inside the next 90 days, we are laying plans to double our minimum and we are confident we will have all the business we can possibly handle in 1922 and more.

"In expanding our resources at this time, we are producing a new car with labor and materials purchased at present day costs."

Resources of Earl Motors, Inc., will include nine plant buildings and equipment covering 53 acres of floor space in Jackson, Mich., and an additional assembly plant located at Brockville, Ont., which has been producing cars for Canada and the British dominions.

The board of directors as now constituted consists of Earl as president; John Fletcher, vice-president of the Fort Dearborn National Bank, Chicago, treasurer;

directors, H. F. Wardwell, president of the Burnside Steel Co., Chicago; L. B. Patterson, vice-president of the Edward Tilden & Co., Chicago; Horace Delisser, chairman of the Ajax Rubber Co., New York City; Wallace G. Kay, Kay & Co., Detroit; J. Fletcher Farrell, Sinclair Refining Co., New York; J. Wissenback, Chicago, and L. E. Latta, secretary.

The factory executive personnel includes Kelly R. Jacoby, vice-president in charge of sales; J. R. Findlater, vice-president in charge of Pacific Coast territory; Walter J. Mery, comptroller; David Minard Shaw, advertising manager; Allen T. McKay and R. M. Cowham, assistant general sales managers; Clarence L. Thurston, export manager; Victor Jantsch, chief engineer; W. B. Jameson, general factory superintendent; C. A. Woodruff, purchasing agent; J. L. Blyth, director of service; R. M. Chapman, assistant secretary; Leroy C. Allen, assistant treasurer and W. M. Zerby, traffic manager.

### Built Up Willys

Earl is 47 years old and started his business career with the American Hardware Co. of New Britain. With this company he advanced to the position of vice-president, which he held until he resigned to become vice-president and general manager of the Hendee Mfg. Co. of Springfield. Oct. 1, 1915, he was elected vice-president in charge of manufacturing of the Willys-Overland Co., and until his resignation in December of last year was virtual head of the corporation's interests in Toledo.

The progress that the corporation made during the years of his association attests his ability in the production field as well as his high rank as a manufacturing executive. Soon after the beginning of this association circumstances forced him into fields other than within the immediate scope of manufacturing and resulted in his assuming nominal control of the Willys interests and with general supervision over all matters with the exception of policy and financing.

## Senate to Discharge Federal Truck Debt

WASHINGTON, Oct. 3—Senator Townsend of Michigan has introduced a bill in the Senate for the relief of the Federal Motor Truck Co. of Detroit. The bill would authorize the Government to pay the sum of \$11,117.78 to enable the company to pay and discharge a liability for that amount on account of certain material purchased by it to be used in the performance of a contract with the War Department, a contract that was thereafter canceled by the Government without provision being made for the discharge of such liability.

## Truck Market Shows Return of Business

### No Curtailment Noted in Passenger Car Plants—Collections Continue Good

NEW YORK, Sept. 30—Business in the automotive field continues surprisingly good considering the fact that September usually is one of the duller months. There has been no material curtailment in production in passenger car plants and the truck market is showing signs of life as is evidenced by the resumption of dividend payments by the Republic Truck Co.

Makers of parts and accessories report that their business for September is better than it was for August. This is particularly true of orders for unit parts such as frames and engines. Sales by parts makers in August were slightly better than in July.

Particularly encouraging is the fact that collections are good and that past due accounts gradually are being whittled down. The volume of notes outstanding is steadily decreasing. The finances of the industry rapidly are becoming stabilized.

### Co-operation Apparent

Retail sales of passenger cars in most sections of the country have remained practically stationary for the past three or four months. The natural tendency from now until the first of the year will be downward but surprising interest is being shown in enclosed models.

There is evidently throughout the industry a keen desire to co-operate. This is demonstrated by the decision of the members of the National Automobile Chamber of Commerce to discuss at their annual meeting this week the question of how they can help dealers finance themselves through the winter and what can be done by manufacturers to help solve the used car problem.

The Automobile Underwriters Conference has accepted the contention of the automotive industry that due recognition has not been given in the past to the "moral hazard" in automobile insurance and that this has been largely responsible for the heavy losses incurred in the past two years.

## Marked Gain Shown By Willys-Overland

**Present Daily Output 300 Cars—  
Recent Payments Reduce Loans  
to Less Than \$20,000,000**

TOLEDO, Oct. 3—Retail sales of Overland and Willys-Knight cars have made a marked gain since the last price reduction and since a reorganized sales policy has been announced to some of the dealers. Sales for the first three weeks in September were 223% as compared with the same period in the previous month. Shipments from the factory increased 116% over the same period in August.

Along with the increase in general business has come considerable betterment in the financial position and the company officials are looking forward to a year of capacity business beginning next March. The changes made in the sales policy are quite revolutionary and have not been fully announced as yet.

### Efficiency Increased

It is understood, however, that most of the distributors of the company will be eliminated and the intermediate profits divided between the factory and the local dealers. This action follows the complete survey made of the field by President John N. Willys, who has been on the road for several months. He has increased representation of the Overland products by 410 dealers scattered throughout the country. It is hinted that the new alignment of dealer policy will be an economical change for the factory and result in placing Overland dealers in a position to meet competition with a big increase in business.

Production at the present time is 300 cars a day. The organization of factory methods under the management of Vice-President Charles B. Wilson has resulted in increasing efficiency so that 2.55 Overlands are now being produced with the same number of men as were formerly required to make one car.

Officials report that they have on hand cash amounting to \$8,000,000 and that loans have been cut to less than \$20,000,000 with recent payments. Inventories have been reduced to about \$18,000,000. When market conditions become more stable this item will be reduced to less than \$15,000,000.

### Distributors Dropped

NEW YORK, Oct. 3—Confirmation has been obtained of reports current for the past ten days that the Willys-Overland Co. had decided to eliminate distributors from its merchandising organization although no official statement has been made by the corporation. It is assumed that the purpose of this radical change in policy is to produce more intensive sales effort on the part of the dealers.

It is understood that Guy Simon in Detroit and one or two other distributors will be retained. Harry B. Harper,

president of the Overland-Harper Co. of Philadelphia and former president of the National Automobile Dealers' Association has turned over his large holdings in Philadelphia to the factory.

A considerable number of new factory branches will be established and in nearly every case this territory will cover several States.

The new Philadelphia branch of Willys-Overland, succeeding the Overland-Harper Co., will be managed by George D. McCutcheon, who has been head of the Denver branch. Before going to Denver McCutcheon was branch manager for Buick at Atlanta.

## Drake Is Appointed to Advise on Census

WASHINGTON, Oct. 4—J. Walter Drake, president of the Hupp Motor Car Corp. and director of the National Automobile Chamber of Commerce, has been named a member of a committee of trade and craft organizations to confer with the Bureau of the Census regarding a general schedule for manufacturers for the census of 1921. This committee is the outgrowth of conferences here in July with Secretary Hoover and officials of the Census Bureau. Modifications of the tentative schedule, which has been devised by the Census Bureau, will be suggested by this committee.

Because of its simplicity, the new schedule differs from past schedules and also varies with regard to the amount of information called for. As outlined, the new schedule covers the following items: Name and particulars of establishments as to location and lines of products; persons employed as salaried employees, including managers, clerks, etc., and wage earners, including piece workers; time and operation and products which will be detailed for the particular industries.

## 13 New Names Appear on New York Show List

NEW YORK, Oct. 6—Ninety-three companies manufacturing passenger automobiles will draw for space in the New York show at headquarters here of the National Automobile Chamber of Commerce this afternoon. Thirteen new names appear on the list and eight which have shown heretofore will be absent. The new companies are: Stanley Motor Carriage Co., Noma Motor Corp., Leach-Biltwell Motor Car Co., Cortland Cart & Carriage Co., Bournonville Rotary Valve Motor Co., Essex Motors, Yellow Cab Mfg. Co., C. H. Wills & Co., Handley-Knight Co., Durant Motors Co. of N. Y., Inc., Rickenbacker Motor Co., Kelsey Motor Co. and Ogren Motor Car Co.

The companies which have had displays at the show heretofore and which will not participate this year are: Allen, Brewster, Cunningham, Daniels, Lorraine, Piedmont, Scripps-Booth and Winton.

## Locomobile Works Through Branches

**Company's Program Provides for  
Production of 4 Cars Daily  
and New Prices**

BRIDGEPORT, CONN., Oct. 3—Approval has been given to the plan for the continued operation of the plant of the Locomobile Co. here following the termination of the contract between the company and Hare's Motors, which had been in charge of the property for the last eighteen months.

The announcement of the company's program carries also a new schedule of prices made possible through modifications in the costs of labor and material. These prices are as follows:

	Old Price	New Price
4-passenger touring.....	\$8,600	\$7,600
7-passenger touring.....	8,600	7,600
Limousine .....	10,000	9,150
Sedan .....	11,700	11,000
Cabriolet .....	12,000	10,700
Coupe .....	11,400	10,500
Sport type (Double Cowl)	10,700	9,500
Landulet .....	10,000	9,150

### No Distributors

Under the new plan the company in merchandising its product will sell either through factory branches or dealers trading directly with the factory. It is understood that production will be limited to four cars a day. The factory is ample to take care of such a schedule.

Election of officers has resulted as follows: Elmer H. Havens, president; F. R. Hickman, vice-president and treasurer; E. A. Travis, general sales manager, all Bridgeport residents. Havens is a banker, prominent in the iron and steel industry in New England. His election has been in behalf both of the stockholders and of the other financial interests identified with the continued operation of the plant. Hickman was formerly identified with the company, having been in charge of its finances for many years. Likewise Travis returns to a post he filled for many years.

### Plans Outlined

In a statement of the company's plans, embodied in a letter to the trade, Travis says:

"We desire to assure you that our plans call for strict adherence to the best traditions of the Locomobile company. We take justifiable pride in the prestige our product has earned through the years of pursuit of a well-defined policy of concentrating all our efforts upon a very limited number of vehicles, and building that number supremely well.

"We contemplate no radical changes. We shall build only the one chassis, the '48,' mounting upon it the standard types of coach work with which you are familiar; also designing through our custom body department particular types of bodies for patrons whose requirements are not met by our standard coach work. Our plans call for a gradual extension of the present activities in our plant."

## Fisk Gets Contract To Tire Durant Cars

**No Fixed Number Stipulated—  
Record Established in Getting  
New Car on Market**

NEW YORK, Oct. 3—Durant Motors, Inc., has signed a contract with the Fisk Rubber Co. under which all its four cylinder and six-cylinder models will be equipped with Fisk tires, both cords and fabrics. The clincher quick detachable type will be used. The rear wheels of inclosed jobs will be equipped with cords. No fixed number of tires is provided for in the contract but they will be supplied as needed.

### Competition Keen

There was keen competition for the Durant tire contract and negotiations have been under way for months. Several statements have been made unofficially crediting various companies with having obtained the business. Reports were heard some time ago that F. A. Seiberling, former president of the Goodyear Tire & Rubber Co., might become associated with Durant in the production of tires. It is understood there were some conversations on this subject but nothing came of them.

The Long Island City plant of Durant Motors, Inc., has gone into quantity production this week and is turning out from 50 to 60 cars a day. Actual production on a considerable scale was started Sept. 27. Ten cars were turned out that day and 13 the next. The output has steadily increased since then and it will be expanded as rapidly as possible.

Durant is proud of the showing made in getting the Durant Four on the market seven months after his engineering staff got to work on it. This is said to establish a record.

### Lansing Starts Nov. 1

Credit of this achievement is given to F. W. Hohensee and A. P. Sturt, the chief engineer. Both these men went with Durant from Chevrolet. It was Hohensee, who was general manager of production, who was responsible for getting operations under way on a quantity basis in the Chevrolet plant at Tarrytown in less than two years. This was regarded as a record until he took over the Durant job. The experience gained in the Chevrolet undertaking was used to the best advantage in Long Island City. While installation of the conveyor system at Tarrytown took seven months it was only a matter of weeks in the Durant plant.

Production in the Lansing plant will start as scheduled Nov. 1. A few men are being taken on every week in the Muncie plant of Durant Motors of Indiana, formerly the General Motors Sheridan factory. The work of redesigning the Sheridan which will be known as the Durant Six, is nearing completion but no date has been set for beginning production at Muncie.

The Durant organization considers the

fact that it is now in quantity production sufficient answer to the contention of the Illinois Securities Commission, which has refused to allow the sale of Durant stock in that State on the ground that it is purely speculative. It might be stated that no formal application ever was made for permission to sell stock in that State, although inquiry was made as to what procedure was necessary and some stock was sold there.

The report from Springfield, Ill., that Durant Motors was refused incorporation papers is without foundation. The company never has made application for incorporation in Illinois and has no intention of doing so.

Friends and admirers of Durant are pointing to the fact that he has accomplished in the present period of depression a feat similar to that he put over in the panic period of 1907 when he went right ahead with construction work on the great Buick plant which at that time was the largest automobile factory in existence. He was warned at that time that there would be no possible market for the number of cars the plant was designed to turn out but disregarded this advice and went serenely ahead in the firm belief that there were unlimited future possibilities for the sale of automobiles.

It is significant that development of his present venture began after the period of depression was well under way and it is equally significant that his first factory is getting into production just as the corner has been turned and the business outlook is decidedly more hopeful.

## Grand Prix Entrants Restricted by Ruling

PARIS, Sept. 22 (*By Mail*).—A piston displacement of 2 litres (122 cubic inches) has been adopted for the 1922 Grand Prix automobile race. The cars must weigh not less than 1653 pounds and the distance to be covered will be about 310 miles. This rule automatically eliminates all foreign competition. The French club has adopted as a basic principle that the race shall only be held if the competitors are 33 per cent French. With the 22 cubic inch rule for 1922, they are guaranteed a 100 per cent French race.

In addition to the speed test for purely racing cars, an interesting touring car race will be held on a limited fuel allowance. Officially known as the Touring Grand Prix, the race will be for a distance of 500 miles with four-passenger sporting type cars, having minimum body dimension, running on an allowance of gasoline equivalent to 13.8 miles per American gallon.

### NO NEW ROLLS-ROYCE

LONDON, Oct. 3 (*By Cable*).—Rolls-Royce, Ltd., denies reports that it has ready for production a new four-cylinder 20 hp. car. The model which has been built is being used only for experiments as a part of the company's research program.

## Predicts Few Types by British Makers

**Lanchester Head Believes Individual Character of Automobile Will Be Continued**

NEW YORK, Oct. 4—George H. Lanchester, who for 12 years has been responsible for the development and design of the Lanchester car manufactured by Lanchester Motor Co., Ltd. Birmingham, England, has been in America for several weeks studying the requirements of the American market for high priced automobiles. Lanchester is a brother of Fred W. Lanchester of worm gear fame and considered one of the leading engineers in Europe and one of the best mathematicians in the industry.

### No Mass Production

George Lanchester believes that the individual character of the British automobile, which was a dominant feature previous to the war will be continued notwithstanding much that has been said since the armistice on British companies undertaking mass or quantity production of automobiles. So far the British concerns that since the armistice have aimed at quantity production have not succeeded, and Lanchester does not believe there is much possibility of any English concern succeeding in quantity production in the sense that American makers have carried it on.

Lanchester looks for a continuation of the individual character of car by the British manufacturer, and believes the strength of the British industry lies in this individuality. He believes that the majority of British firms will specialize on one or two models at the most, and that the wide range of models which characterized British makers previous to the war will not be continued, although at the present time there are several British manufacturers who are adding smaller models to their present wide line. Lanchester believes that this is merely a temporary situation due to the depression in the high-priced market and that some of the manufacturers are taking advantage to experiment with the smaller car field.

### Lanchester Car Pioneer

The Lanchester car, which has always been a leader in individuality in the British field, was a pioneer in cantilever spring suspension, having used this form continuously since 1901. The use of a three-speed forward planetary gearset has also been a distinguishing feature. It has used the hour-glass type of worm-driven rear axle for many years, which was developed by Fred Lanchester, whom the industry recognizes as the father of worm drive. The Lanchester car, a six-cylinder design, with cylinders 4 x 5 in., is marketed in two wheelbases, 130 in. for four-passenger cars and 150 in. for other models. The chassis price is £1,950 for either wheelbase.

## Allen Creditors Vote To Liquidate Affairs

**No Financial Interests Found to Underwrite \$1,000,000 Necessary to Continue Operations**

COLUMBUS, Oct. 3.—At a meeting of the creditors of the Allen Motor Co., which has been in the hands of George A. Archer and William C. Willard as receivers for almost a year, a decision was taken to liquidate the affairs of the concern. This decision was made because of the difficulty of disposing of cars of a company under receivership.

This action was in line with the recommendation of the receivers, who submitted a report on the operation of the plant and the business since they have been in charge. It is claimed that more than \$1,000,000 additional capital would be necessary to finance the company properly if it was decided to continue operations. No financial interests have been found that would undertake to underwrite that amount.

The claims against the company are approximately \$1,900,000 although the amount is not fixed because of contingent liabilities as a result of many contracts for parts and bodies. All of the larger creditors were represented at the meeting. Judge Oscar W. Newman and Judge Schroth, representing the receivers have tried to finance the company so that it could continue. Application will be made to Judge J. E. Sater in the Federal Court for permission to sell.

## Olympia and White City Exhibitors Total 520

LONDON, Sept. 20 (By Mail).—Against an entry of 750 exhibitors for the Paris show next month, Olympia and White City for the November show have a total entry of 520. Car exhibitors will number 139, body building exhibitors 55, tires and wheel makers 39, and accessory and component makers and importers 266.

At the forthcoming Commercial Vehicle Show, Oct. 13-22, there will be 76 exhibitors of vehicles, 92 exhibitors of accessories and components, and 23 of tires and wheels.

There will be closed order as to price of cars and carriage-work ruling during the car show, meaning that the prices published in the official catalogs are to remain untouched for the period of the event. Another rule cancels the erst-while facilities for trial runs and re-entry to the exhibition. As at last year's show admission to either section of the show will frank the holder of the card of admission to and from both sections free of cost including the journey from or to White City and Olympia.

### KENNERDELL RESIGNS

NEW YORK, Oct. 1.—Richard Kennerdell, Franklin, Pa., who for eight years has served as chairman of the contest

board of the American Automobile Association, has placed his resignation in the hands of President George Diehl, to take effect immediately.

Chairman Kennerdell during his eight years has been a strong supporter of clean motor contests and his resignation at this time, due to differences of opinion with President Diehl, is a matter of regret. Former Chairman William Schimpf, of Brooklyn, N. Y., who preceded Kennerdell, has temporarily assumed the chairmanship.

## Ohio Farmers Active in Light Truck Field

COLUMBUS, Oct. 3.—With the coming of colder weather and a slight improvement in industrial conditions, increased inquiries for motor trucks are being received by Columbus and central Ohio dealers. A better tone appeared shortly after the first of September and has been improving since then.

During the dull period there was some business in the light delivery wagons and lighter style of trucks, but the heavier vehicles were very dull. Now there is a decided activity in the heavier lines of trucks, including those of 2½ to 5 tons. Despite the restrictions on the use of trucks which limits the weight and load to 10 tons, deals are frequently made for the purchase of 5-ton vehicles. Owners are confident that the coming session of the Ohio General Assembly will amend the law to make the maximum load 12 tons as it is in many States.

Farmers are showing a disposition to buy trucks, although not of the heavy varieties. The usual farm truck is the 1½ to 3-ton sizes. Farmers have not had as bad a year as they had believed and the corn crop as a whole has come out well.

## Dealer Organization Increased by Liberty

DETROIT, Oct. 3.—Liberty Motor Car Co. is increasing its dealer organization following a change in distribution plans affecting several important localities. Latest appointments include dealerships in Syracuse, Houston, Wilkes-Barre, Pa.; Pittsburgh, Springfield, Ill.; Terre Haute, Vincennes, Danville, Troy, N. Y., and Windsor, Ont. Spotty business conditions are found by the company throughout the country, though Southern business as a whole is reported better. Open car business is holding up surprisingly for the season of the year, the company ascribing this to popularity of sport models.

### HANDS BACK WITH LIGHT CAR

LONDON, Sept. 29 (By Mail).—G. W. Hands, founder of the Calthorpe Motor Co., Ltd., at Bordesley, Birmingham, will produce a two-seater light car with dickey seat to retail about \$1,500. It is promised for the Olympia Show period. Hands has motorcycle interests also. The present Calthorpe is one of the best known modern light cars.

## Australian Buyers Expect More Cuts

**Wool Situation Which Has Been Retarding Sales Factor Shows Improvement**

SYDNEY, AUSTRALIA, Aug. 24.—Although most of the automobiles have been reduced in price 50 to 60 pounds sterling or \$250 present exchange, this has not caused any stimulation in sales as buyers are looking for something more in price reductions. At the same time most of the automotive dealers in Australia are getting low in stocks of cars, which perhaps accounts for the small price reductions, the majority of the dealers feeling that it was not necessary to make a sacrifice with so small a stock. There are exceptions where some importers are heavily stocked.

Perhaps the main factor retarding the sale of automobiles has been the inability to sell Australian wool. The farmers have not yet recovered from their losses of the previous years. The wheat farmers have all they can do to meet their financial obligations. This year the whole of Australia is well under crop and while some of it has been severely damaged by excessive rains, the average conditions are good. If the farmers receive one-half as much per bushel as a year ago they will be well satisfied and many will be in a position to buy automobiles. It is estimated that about 50,000,000 pounds sterling represents the amount of money the wheat crop will bring and this will have a similar influence in stimulating recovery of trade throughout Australia.

In the wool market prices are a little higher than pre-war prices and are considered satisfactory. Another factor that is improving the wool situation is that the shares of the British Australian Wool Realization Association, Ltd., have been made negotiable on the stock exchange. This association has issued shares to all holders of unsold wool representing the value of the wool so held and after the wool is sold the shares are liquidated or bought back by the B. A. W. R. A. This has aided in the recovery of business and automobiles have commenced to move as a result.

## 49 Per Cent Franklins Are Enclosed Models

SYRACUSE, Oct. 3.—During the first eight months of this year 49 per cent of the cars shipped from the factory of the Franklin Automobile Co. were of the enclosed type, an increase of 9 per cent over the corresponding period in 1920.

Officials of the company say that the demand for enclosed cars is not confined to cities and towns of the North where the climate is severe, for a careful analysis made by factory statisticians has shown that the sedan type is equally popular in California and Maine and in rural sections as well as in cities.

## Standard Parts Asks To Pay New Dividend

Permission Sought to Distribute  
Among Creditors Second  
\$1,000,000 in 60 Days

CLEVELAND, Oct. 3—The Standard Parts Co., through Receiver Frank A. Scott, has applied to the United States District Court here for authority to pay the creditors another 10 per cent dividend on their claims. The corporation has been in the hands of receivers for more than a year, and Scott's application is received in the financial district as another distinct step toward the ending of the receivership.

If Federal Judge D. C. Westenhaver passes favorably on the application, the company will distribute to creditors \$1,000,000. Approximately 60 days ago Scott distributed another like amount. After paying these \$2,000,000 it is announced that the company will have left in the treasury ample working capital. A hearing on the application to pay will be held on Oct. 15.

### Claims Reduced

Undisputed claims against Standard Parts aggregate \$9,197,000, while there were contingent liabilities of \$1,250,000. These, the application states, have been reduced through adjustments by \$510,000 and the receiver believes they will be reduced further. As a result the total claims against the company are placed at approximately \$9,500,000.

There is good news for the small creditors of the company in the application, for the court is asked for permission to pay in full all claims not exceeding \$100. There are 748 such claims, aggregating \$22,619.

Creditors some time ago proposed a plan whereby they would take over the plant, and at the hearing on the initial application for authority to distribute a 10 per cent dividend, a determined effort was made to have the plan adopted, but it failed. The favorable showing made by the receiver is expected to end all efforts on the part of creditors to take over the plant, especially as stockholders regard the plan unfavorably.

The company is receiving many inquiries for its various products, and one of the factory executives says business conditions are very healthy. "We are going into the winter confident that parts and accessories business will steadily grow, and also with the realization that our customers' shelves are practically empty," he states. The company has one or two plants for sale, but the two dividends were paid from liquidation of inventory and factory operations.

### DEALERS ASK BANKRUPTCY

NEW ORLEANS, Oct. 3—Frank & Weinberger, composed of Theodore Frank and Frank Weinberger, who are the local agents for the Premier and Velie cars, have filed a petition in volun-

tary bankruptcy in the United States District Court here through their attorney, Bertrand I. Cahn. The petition lists the liabilities at \$426,846 with assets of \$144,625. Among the larger New Orleans creditors are the Hibernia Bank with a claim of \$90,000, Marine Bank \$20,000 and the Citizens Bank with a claim of \$11,000.

## No Excessive Stocks Held in South Africa

NEW YORK, Oct. 1—Improving conditions in South Africa, with denials that excessive stocks of cars are held in the customs houses, are reported by the National Bank of South Africa. From Pretoria, the bank reports as of July 30 that the Motor Traders' Association has experienced somewhat better conditions in its sales and the stocks of cars are being liquidated, members of the association having reached the stage in some cases when they will have to begin importing again.

"In view of the damaging effect produced by exaggerated reports as to the number of cars in bond at the coast, and more particularly at Cape Town, a member of the association made extensive investigations in the early part of the month (July) and discovered that the total number of cars in bond at Cape Town was only 360," the bank states. The five months ending May 31 saw the importation of 1052 cars, valued at \$371,863, as against 4187 valued at \$1,065,945 during the same period last year.

## Tractor Sales Grow Under Harvester Drive

CHICAGO, Oct. 3—Tractor sales under the force of the International Harvester Co.'s "Tractor-a-Week Drive," one for each of its branch houses, are showing an increasing number and the drive is a success. As a result of this concentration of sales forces on one line there has been a noticeable drop in other lines handled by the company. For instance, motor trucks, which were selling at the rate of 100 a week before the tractor drive was started, have fallen off to 80 and 85 a week.

On the assumption that there will be a decrease in the price of building materials of perhaps 10 per cent between now and spring, it is announced that there will be no work done on the large new factory of the International Harvester Co. at Fort Wayne, Ind., this year.

### ALL-AMERICAN NOT SOLD

CHICAGO, Oct. 3—The factory site and buildings of the All-American Truck Co. was not sold at auction Thursday, as advertised. A second mortgage for \$50,000 controls the situation and the real estate will go to the holder of this claim. This is the third time the company has been in receivership and this settlement of the concern's affairs is said to mark the end.

## Favors Wadsworth Bill for Air Control

Satisfactory as Emergency Measure, Coffin Tells S. A. E. in  
Urging Legislation

DETROIT, Oct. 3—The Detroit section of the S. A. E. was urged by Howard E. Coffin at the first fall meeting to take early steps toward recommending to Congress the necessity for immediate action on legislation establishing control of the air. Enlistment of private capital in development of commercial air service, he said, cannot be successfully negotiated until such legislation is enacted.

Coffin commended the bill introduced by Senator Wadsworth of New York as satisfactory from an emergency standpoint, while awaiting the formal report of the American Bar Association on the status of air control. To-day, he said, "the only law effective in this country affecting aviation, is the well known law established by Mr. Newton several hundred years ago."

### Laxity Criticized

He criticized the laxity which to-day permits anyone to fly any sort of plane, comparing this with the care exercised in the supervision of elevators in buildings. His talk preceded a showing of the official Army and Navy motion pictures portraying the sinking of the German war ships by Army and Navy air craft.

Dr. H. C. Dickinson of the Bureau of Standards, Washington, spoke on the activities of the department in automotive research and asked for the co-operation of the private research departments of the factories in reaching conclusions. He said much of the study is of general character and should be accessible for the benefit of the entire industry.

The Detroit section will vote at the November meeting on the question of affiliating with the other engineering societies of the city in a general organization, with a central headquarters and a paid secretary. The views of the national society in regard to a movement of this kind will be sought in the meanwhile and announced at that time.

## Deny Myles-Standish Injunction Petition

TOLEDO, Oct. 1—At a hearing in Denver before the Circuit Court of Appeals the Myles-Standish Co. sought leave to ask the District Court for a modification of the sweeping injunction for unfair competition that was granted to the Champion Spark Plug Co. in the U. S. District Court at Omaha on Dec. 3, 1920. The court denied the petition of the Myles-Standish Co., leaving in full form and effect the injunction entered by the District Court.

## White Readjustment to Aid Production

### Automotive Business in Cleveland District Continues to Evidence Upward Trend

CLEVELAND, Oct. 3.—Business is going steadily forward in the Cleveland district, according to many signs that may be read easily.

The White Co. is making certain readjustments in its plant that it was unable to make during the war period or the years immediately following, owing to pressure of business. During this time extensions and additions have been erected which have increased the total floor area from 406,371 sq. ft. in 1914 to 1,271,181 sq. ft.

#### Sales Plan Successful

In preparation of an early return of normal business a rearrangement of methods is in progress for the purpose of facilitating production, thus placing the company in a better condition to meet requirements. Since the sales department was placed in the hands of a committee of four vice-presidents, each with a definite territory, results have been more satisfactory and August sales were 10 per cent in excess of those for July. September business is keeping up.

The truck business is improving, which is taken as an indication that all lines are in on the revival. The International Truck Corp., for instance, sold more Mack trucks in September in Cleveland than it ever did in any other month in history of the organization.

#### Parts Business Does Well

Secretary A. O. Williams of the Cleveland Automotive Trade Association, which is a clearing house for reports on business, says that the parts and accessories business is going well. The Poulson Rubber Co., which manufactures tire accessories, is working night and day at its plant. The Sterling Manufacturing Co., producing the Sterling ammeter, has more orders than it has facilities for manufacturing at present. The Pennsylvania Rubber Co., the A. J. Cooper Co., the M. & M. and Philetric report that salesmen are bringing in orders and that there is no longer the grind and strain that was felt some time ago in doing business.

As for the retail business, the Nash-Ohio Co. is behind with deliveries; the same is true of the Paige, Packard and Buick 4. The Dodge agency sold more trucks in September than it has done in any previous month of the local company's history.

#### BLACK & DECKER SALES PLAN

BALTIMORE, Oct. 3.—An arrangement to sell its product on a time payment basis has been made by the Black & Decker Mfg. Co. The plan, which was put into operation Oct. 1, permits dealers, garagemen and other users of the

company's products to buy them on the basis of 23 per cent down and the balance in monthly installments for a six months' period without interest charges. Jobbers, through whom Black & Decker products are sold exclusively, will receive immediate cash payment in full from a banking corporation which is handling the financial end of the plant. In case a buyer wishes to pay cash he will receive the usual discount allowed by his jobber for immediate payment.

### Austin Motors Denies Rumors of Shut-Down

LONDON, Sept. 20 (*By Mail*).—A rumor was afloat on the Stock Exchange last week-end to the effect that the Austin Motor Co. at Birmingham would close part of its works until spring, the inference being that the step was due to lack of orders. Sir Herbert Austin has promptly denied this rumor and has asserted that the business is moving steadily upward.

There is fair hope that the company will maintain its program and chassis types unaltered for two or three years, concentrate on improving details and strive to get down sales costs, which, of course, must be preceded by a drop in manufacturing costs.

### Mexico Gets Largest Shipment of Ford Cars

DETROIT, Sept. 30.—The largest single shipment of Ford motor cars to Mexico was made by the Houston branch on July 26, when 340 cars were shipped to Cia Importadora del Auto Universal, S. A., Mexico City. It is noted in connection with the shipment that special railroad arrangements had been made to speed it along, as under existing conditions in the Mexican money market, it is imperative to get the cars delivered to buyers as quickly as possible.

Foreign automobile conditions are reported brighter by the company. All foreign plants had an output of 6140 for August. At Buenos Aires production made the most important increase that it has for some time. Ford Motor Co. of Canada turned out 2773 cars and trucks. Production in all plants, domestic and foreign, totaled 118,100 for August. Kearny, N. J., had the highest production of the assembly plants, with Detroit second and Philadelphia third.

#### DISTRIBUTOR IN BANKRUPTCY

DETROIT, Oct. 3.—W. D. Block Motor Co., Marmon and Lexington distributor of this city, has filed a bankruptcy petition in Federal Court setting forth liabilities of \$261,691.67 and assets of \$127,294.11. In the petition as filed by Louis F. Dahling, following a stockholders' meeting of Sept. 20 it is declared that "many defaults are occurring in the payment of notes and it is necessary that collection be enforced or the cars recovered from defaulting purchasers." The Security Trust Co. has been named receiver.

## Avoids Receivership By Dealer Contracts

### Suit Dismissed Against Auto- motive Corp., Tractor Manufac- turer Operating Toledo Plant

TOLEDO, Oct. 3.—After the Automotive Corp., Toledo, manufacturer of tractors and about to place upon the market a small light automobile, had shown that it had valid dealer contracts for \$2,500,000 worth of tractors, a suit, brought by a stockholder in Federal Court asking for a receiver, was dismissed.

Previous to this action the officers of the company against whom state warrants charging violation of the "blue sky" law had been sworn were released from this charge by the municipal court here where the cases were marked off the docket.

President Hulin of the corporation produced the books of the company at the hearing before Special Master Fordyce Belford. After this an agreement was drawn by which the case was withdrawn by the stockholder and he was guaranteed release from all liability for damages arising out of the bringing of the suit.

The company has a new plant here. It has manufactured only a few tractors and is not operating up to production at the present time.

### National Tractor Show Is Postponed a Week

CHICAGO, Oct. 3.—The dates for the seventh National Tractor Show and Educational Exposition to be held in the new exhibition building at the Minnesota State Fair Grounds, Minneapolis, have been changed from Jan. 30 to Feb. 4, to the following week, Feb. 6 to 11 inclusive.

The dates originally fixed made a conflict with the Chicago Automobile Show, the result of which would have been that some accessory and parts manufacturers would be compelled to choose between the two shows in the matter of making an exhibit.

The postponing of the tractor show one week later will avoid this conflict and will make the tractor show run concurrent with the Minneapolis automobile show. It is reasonable to believe that the tractor show will profit to some extent at least by reason of the crowds which will be drawn to Minneapolis for the motor show.

#### SAXON CUT SPURS BUSINESS

DETROIT, Oct. 3.—Decreased prices in Saxon cars effective last week have resulted in a spurt of business which officials believe will continue for some time. Several new distribution contracts have been signed, and the company finds several points now selling where business had been dormant in recent months.

# Production Running on Even Keel

## Bulk of Business In Enclosed Models

### October Plans of Most Companies Impose Heavy Burdens on Body Makers

DETROIT, Oct. 5—Production of cars in the Detroit district during September continued on practically the same basis as August production with a slight decline in low and medium priced cars due, according to executives, to price uncertainty caused by a recurrence of price reductions among a number of important lines.

In the higher priced field practically every company reported increases over August, Cadillac, Lincoln, Packard, Wills-Ste. Claire and Roamer coming under this listing. Packard reports a favorable gain in truck business which promises to be sustained in October. Other heavy duty truck manufacturers also find increased cause for optimism.

Cadillac will increase its output in October to 75 or 80 a day. The new model is declared to be meeting with favorable sales response generally.

Packard will continue its September production of Twin and Single sixes in October.

Lincoln came through with its first 400 month and is looking to better this in October.

Wills-Ste. Claire reports September shipments running as high as 30 daily and looks for continuance in October.

Barley September business surpassed August and the company looks for a 50 per cent increase in October.

Studebaker, which again came through with an 8900, or capacity, month, is the notable exception to the general decrease in the medium priced car field. Sales are holding up strongly and the company looks for high production in October, but it declares difficulty is being experienced in getting enclosed bodies.

With most of the companies the large bulk of October business is going to be in enclosed models and this is imposing a heavy burden on the part of body makers to meet the demand. All of the larger body factories are working to the limit of capacity. An indication of the rush of body business is seen in the fact that despite the opening of the Fisher Ohio Body Co.'s new plant in Cleveland, where bodies for all companies in that district will be made, all of the Detroit plants are in full operation. Briggs Bros. has doubled its capacity by taking over the Everitt plant here. American Body is working extra shifts to meet demands.

Hudson under the influence of lower prices has enjoyed a better sales month

than in August and looks for still further increased business in October following the announcement of its new models. Increased production schedules have been laid down for both Hudson and Essex.

Hupp will increase its production in October after a falling off in sales in September.

Liberty looks for a stronger business in October with the additions made to its sales organization during September.

Saxon also, with an increased distributor organization and a new low price level on its cars, looks for a strong October business.

Reo declares September car business to have been fair but light truck business at a high mark. October business will be benefitted by the introduction of its new models and it looks for a general brightening.

Oldsmobile is pursuing an aggressive sales campaign among its distributor organization, making special effort to promote sales of enclosed cars. September shipments ran at the rate of 55 daily and October business is looked to exceed this if weather conditions are favorable.

Paige during September maintained an average of about 60 per cent of normal in its production schedule, which was under the August average.

Scripps-Booth continues on its schedule maintained during the past several months.

Oakland business after a vigorous start in September, fell off toward the last of the month. The month was the second best the company has experienced this year. October business is expected to react favorably.

Ford Motor Co. finished September with a total of 95,000 cars, a decrease of about 20,000 under August. Sales are continuing high, the company asserts, and 90,000 has been set as the schedule for October. This may be altered, the company declared, to meet either an increase or decrease in sales.

Dort business in September was quiet but general improvement is looked for in October, the South holding out a special field for sales, the company finds, owing to improved conditions in that section and also better weather.

Dodge business in September held to its regular schedule of 550 daily and this schedule will be continued for the first part of October.

### HOLDS SALE CONFERENCE

CLEVELAND, Oct. 4—The annual sales conference of the McGraw Tire & Rubber Co. has been held at the company's general offices here with managers from all sales districts in attendance. The purpose of the meeting was to adopt new distributing policies which have been furnished for the ensuing sales year.

## Jackson Creditors Agree to Combine

### Informed That 14 Companies Will Be Included But Identity Not Disclosed

NEW YORK, Oct. 5—Creditors of the Jackson Motors Corp. agreed at a meeting in Jackson last week to accept the proposal that the Jackson company be included in a proposed \$50,000,000 automotive merger. While they accepted the plan the creditors were left completely in the dark as to the companies with which Jackson will be associated. They simply were informed that 14 corporations would be included in the merger.

The promoters of the consolidation are surrounding their negotiations with secrecy until the plan is presented to the stockholders of the companies whose directors have agreed to the plan. Several companies mentioned in this connection were approached in reference to the combination but declined to enter it.

It has been reported that the Salisbury Axle Co. would be included but this statement was denied emphatically by C. A. Dana, who is president of the Spicer Mfg. Co. which owns the common stock of Salisbury. Strength was lent to the report by the fact that a certificate of dissolution of the Salisbury Axle Co. was filed at Albany a few days ago but Dana explained that this company was an old corporation which preceded the one whose stock they purchased of the Spicer company and that this dissolution was merely a formality. The Spicer company also controls the Parish Mfg. Co. and the same interests dominate the Sheldon Axle Co.

Ralph Van Vechten, vice-president of the Continental and Commercial Bank of Chicago, who was reported to have been prominent in the negotiations for the merger, has telegraphed AUTOMOTIVE INDUSTRIES stating that he has not been connected with the proposal.

## K-W Ignition Loses Suit Against Ford

CHICAGO, Oct. 5—The United States Court of Appeals to-day reversed a decision of Judge A. B. Anderson at Indianapolis, giving the K-W Ignition Co. a verdict of about \$2,000,000 against the Ford Motor Co.

The Ignition company charged that the Ford factory had manufactured for its own use ignition cells on which the K-W company held a patent.

The Appellate Court held that the defendant had not been notified of any infringement of patent rights.

## Uniform Motor Laws Aim of New England

### State Representatives Plan to Lead Way Toward Effecting Agree- ment on Policy

BOSTON, Oct. 3—New England is going to take the lead in efforts to bring about uniformity of motor laws as a result of a meeting here when representatives of the states gathered and listened to addresses on topics along those lines. While the meeting was joined with the National Safety Council, the conference was distinct in that those attending were not members of the organization.

John N. Cole, chairman of the Department of Public Works for Massachusetts in charge of motors and highways, presided. He stated, in outlining the scope of the conference, that motor trucks were the most important part of present-day transportation because of their flexibility.

"Lack of uniformity has caused and is causing more accidents every day than people realize" said Secretary Harry Meixell, Jr., of the Motor Vehicle Conference, New York. "This is due to the fact that it is a most difficult task to get cities, towns, counties and states to agree upon laws where one is required to give away any of its authority to another."

He outlined the Uniform Motor Vehicle law, and told of the movement to interest states in the project. The movement is gaining slowly, and it is expected a number of states will adopt it eventually, because of the vital need for it.

D. C. Fenner of New York, chairman of the motor vehicle conference committee, pointed out that motor truck transportation on the highways could be rendered far more safe if it were made subject to scientific laws uniformly adopted by all of the states and rigidly enforced.

### MAIBOHM MAKES CHANGES

SANDUSKY, OHIO, Oct. 3—The Maibohm Motors Co. announces the following price changes effective immediately:

	Old Price	New Price
5-passenger phaeton.....	\$1,575	\$1,395
Roadster .....	1,575	1,395
Sport roadster .....	1,675	1,395
4-passenger sport.....	1,850	1,595
Coupé .....	2,395	2,295
Sedan .....	2,395	2,295

A year ago the price of the phaeton was \$1,695, with the others in proportion, making a total drop of \$300 in twelve months.

### WHITE HICKORY TRUCKS CUT

ATLANTA, GA. Oct. 4—A 50 per cent reduction has been announced on all models of White Hickory motor trucks, manufactured in Atlanta by the White Hickory Wagon Mfg. Co. This truck is

extensively used in the Southeast. Following is the new scale of prices:

	Old Price	New Price
Model E, 1 ton.....	\$2,450	\$1,225
Model H, 1½ ton.....	2,750	1,375
Model K, 2½ ton.....	3,350	1,675
(150 inch wheelbase)		
Model K, 2½ ton.....	3,450	1,725
(168 inch wheelbase)		

### Davis Reduces Prices on Four of Its Models

RICHMOND, IND., Sept. 30—Effective Oct. 2 the following prices are announced on the 1922 models of the Davis Six, manufactured by the George W. Davis Motor Car Co.

	Old Price	New Price
Touring .....	\$1,895	\$1,695
Sport .....	2,095	1,995
Fleetaway .....	2,150	2,050
Man o' War.....	2,150	2,050

The reductions are from the prices which have been current since last January. Increased production on the three last models together with decreases in the current costs of materials have made the cuts possible. Production at the factory has been steady throughout the year and for the first eight months of 1921 passed the production records for the same period last year.

### NEW REVERE PRICES

LOGANSPOUT, IND., Oct. 5—New prices have been announced by the Revere Motor Car Co. as follows:

	Old Price	New Price
Roadster .....	\$4,850	\$3,850
5-passenger touring.....	4,650	3,850
4-passenger touring.....	4,650	3,850
Sedan .....	6,500	4,500

### ALLEN CARS REDUCED

COLUMBUS, OHIO, Oct. 1—The Allen Motor Car Co. has reduced prices on its touring, roadster and sedan models. The old and new prices follow:

	Old	New
Touring .....	\$1,385	\$1,195
Roadster .....	1,385	1,195
Sedan .....	2,195	1,845

### BEGGS LOWER

KANSAS CITY, Sept. 30—The Beggs Motor Car Co. has made the following reductions on its models:

	Old Price	New Price
5-passenger .....	\$1,775	\$1,520
Coupé .....	2,675	2,320
Sedan .....	2,775	2,420

### GRAMM-BERNSTEIN DROP

LIMA, OHIO, Oct. 3—The Gramm-Bernstein Motor Truck Co. has reduced the price of its Model 10 speed truck from \$1,495 to \$1,365.

### VELIE DOWN

MOLINE, ILL., Oct. 3—Effective immediately, the Velie Motors Corp. announces reductions on its five passenger touring car and roadster, Model 34, from \$1,385 to \$1,235, f.o.b. this city.

## Decreased Thefts Due to Dyer Law

### Vigilance of Authorities Con- tributes to Reducing Number Stolen in 1920 10 Per cent

ST. LOUIS, Oct. 3—Thirty thousand and forty-six automobiles were stolen in 1920 in 28 "index" cities of the country and 21,273 of them recovered, according to the annual compilation of the National Automobile Dealers' Association. The number stolen was 3012 less than the number stolen in 1919 but was 2001 more than the number stolen in 1918. In 1918 cars unrecovered were 21 per cent of the number stolen; in 1919 they were 26 per cent and in 1920 29 per cent.

Chicago took the lead from New York with the number stolen, although a higher percentage of cars remained unrecovered in New York. New York had 5179 stolen; Chicago 5527. New York recovered only 2717 of her stolen cars while Chicago recovered 4340. Dayton had the unusual record of having recovered more cars than she had stolen.

The Pacific Coast cities kept up their yearly good work of recovery. There were 4877 cars stolen in Los Angeles, San Francisco, Oakland, Portland and Seattle and 4175 recovered. The unrecovered cars were 16.4 per cent of the total stolen, or approximately 50 per cent of the average for the country.

The number of thefts in the cities covered decreased 1919-1920 about 10 per cent while the general increase in the number of automobiles throughout the country was about 20 per cent during the same period. A considerable part of this decrease is attributed by the N. A. D. A. to the deterring effect of the national motor vehicle theft law (the Dyer law) which was put through Congress at the instance of the N. A. D. A. and to more stringent laws in the States for the punishment of motor car thieves.

However, a good part of the better showing is due also to vigorous activity of the peace authorities.

The subject of theft is being watched vigorously by the N. A. D. A. and the N. A. C. C. because of the theft insurance rates now having become so high.

### American Bosch Occupies Own Home in New York

NEW YORK, Sept. 30—The new home of the New York branch of the American Bosch Magneto Corp. is a ten-story building erected in the center of automotive sales and manufacturing interests in the city. It is of fireproof construction, being built of steel, stone and concrete throughout. Four of the floors are occupied by the corporation and the upper parts of the building will be rented exclusively to automotive concerns. A large service station and installation garage is located in the basement and the sales and stock rooms, occupying the ground floor, are spacious.

## Moline Equity Kept By Willys-Overland

Will Be Considerably Diluted  
According to Statement of  
Banker Interested

NEW YORK, Oct. 5—Since the plan for the reorganization and refinancing of the Moline Plow Co. was announced there have been persistent reports that "Willys is out of Moline." It can be said on authority that John N. Willys personally never was interested in the plow company except as a subsidiary of the Willys-Overland Corp. Under the reorganization Willys-Overland will retain its equity in the Moline Plow Co. but as one of the bankers interested expressed it, "this equity will be considerably diluted."

In September, 1918, G. A. Stephens, former president of the Moline Plow Co. made an announcement which said:

"The Stephens interest, except F. G. Allen and family and F. G. Allen remaining in charge of the business, have sold their holdings in common stock to John N. Willys for \$150 per share and will receive in payment therefor stocks paying 7% cumulative preferred dividends quarterly, in following proportions of the following companies: Willys-Overland, 55%; Electric Auto-Lite Corp., (now Willys Corp.), 30%; Curtiss Airplane & Motor Corp., 15%.

"The Stephens family has arranged with the purchaser of their stocks that the opportunity is offered to all holders of the Plow company common stock to exchange their stock for the above stocks in the proportion mentioned, and to receive the above stocks in the ratio of 1½ for their common stock.

"The Willys-Overland Co. reserves the right in the case of fractional shares to pay either scrip or cash. It is part of this agreement that dividends on the three preferred stocks mentioned shall accrue from the date of agreement, Sept. 6, 1918. We are advised that the policy of the new management will not be to pay cash dividends on the common for a period of years in order to permit improvements of plants, to take care of the largely increased output and the building up of sufficient reserve and to safeguard this extended business."

As a result of these negotiations the Willys-Overland Co. acquired slightly more than 82 per cent of the Moline Plow Co. common stock.

On the basis of \$150 a share, the Stephens interests received \$12,300,000 worth of Willys securities. Since that time there has been a very material decrease in the value of the Willys stocks. In the absence of any definite information regarding the amount of stock he owns personally in his own companies it is impossible to estimate the personal losses of Willys on the Moline transaction.

## Good Winter Business Sighted in Arkansas

LITTLE ROCK, ARK., Oct. 3—Automobile men in this section of the country are now breathing the air of refreshing optimism. While most sales have been of the more conservative

priced cars, there have been many high-priced cars sold, and dealers over the State are expanding by making improvements and adding new lines, and evidently planning for a big fall and winter business. The cotton and rice crop is coming along and is bringing a good price.

Dealers report that collections are decidedly better, with cash not as hard to get as in the summer. Three months ago it was predicted that not more than 35 per cent of the 1920 debts would be liquidated. At present there is every indication that payments will exceed 75 per cent and that this year's cotton and rice crop, with other farm products, will aid very materially in putting men, who have been carrying burdens of debt, back on a sounder financial footing.

## Collins Obtains Peerless Control

(Continued from page 686)

significant fact that during his entire service there was never even a suggestion of a strike or labor disturbance of any kind in the Cadillac plant. This record resulted from his intimate, personal co-operation with his co-workers in all departments, which created a spirit of loyalty in the manufacturing and selling organizations.

Collins began his automobile career back in the early days of the industry as general manager of the Kansas City branch of the Buick Motor Co. He directed Buick distribution in this important territory with such pronounced success that, three and one-half years later, he was called to Flint, to assume the bigger responsibilities of general sales manager of the Buick company. His achievements in helping to rehabilitate the Buick company, in improving the car, strengthening the factory and distributing organization, multiplying Buick sales many times and putting Flint on the industrial map, have already been recorded among the most sensationally successful accomplishments in automobile history. He later was appointed assistant to W. C. Durant as president of General Motors Corp., maintaining offices in New York and Detroit for the management of the large affairs of the corporation, before becoming president and general manager of the Cadillac Motor Car Co.

On two previous occasions the control of Peerless changed. In 1915 it passed to a New York City syndicate headed by Harrison Williams. The preferred stock was purchased for \$105 a share and the common stockholders were paid \$175 a share and in addition a \$50 bond per share. In 1918, B. G. Tremaine, F. S. Terry and certain associates went into the open market and purchased back control of the company, the managing interest thereby returning to this city. The plant during the boom times of the war and immediately following had 400 men on the payroll. Tremaine retires from Peerless to devote all of his time to the business of the General Electric Co.

## INDUSTRIAL NOTES

Clark-Turner Piston Co. of Los Angeles is establishing factory branches at important distributing centers throughout the country with the purpose of effecting a twenty-four hour service. Appointments of these distributors who will handle warehouse stocks cover Kansas City, Freeport, Ill., and New York City, with another to be made for the Southern States.

The American Motor Parts Co. is transferring its unit from the R. & V. motors plant at East Moline, Ill., to the new factory located in the Ideal Milling Co. plant, with no appreciable reduction in its production schedules. R. & V. Motors disposed of a large section of its plant to the Troy Laundry Machine Co., which is now taking possession.

Ajax Rubber Co., Inc., is operating its Trenton, N. J., plant at practical capacity with three eight-hour shifts a day, and its Racine, Wis., plant somewhat slower on a two eight-hour shift basis, representing a substantial increase over earlier in the year. Shipments are said to equal production with finished goods on hand at the lowest point possible.

The Fulton Tractor Co., a new organization to manufacture a tractor invented by J. F. Fulton which uses no cog gears, has purchased the plant of the American Window Glass Co. at Anderson, Ind. Production of twenty tractors a day at the end of a ninety-day period is promised by the company, which also asserts that it is fully capitalized.

The Raleigh Motors Corp. of Bridgeton, N. J., manufacturer of the Raleigh car, has secured a plant at Reading, Pa. J. R. Sutterlee, president; Leroy Sutterlee, secretary and George Quimby, production engineer, who visited Reading recently, state that they will start production as soon as their equipment arrives and the plant is remodeled.

B. F. Goodrich Co., Akron, shut down the first three days of October for inventory taking purposes. It is believed that following this production will be gradually increased to a more normal basis.

The Eagle Motor Truck Corp. has dedicated a large addition to its plant in St. Louis. Invitations were extended to all stockholders, truck owners and operators in the city.

Kearney & Trecker Corp., Milwaukee, has removed its New York branch office to Room 371, the Hudson Terminal Building, 50 Church Street, New York City.

Buckeye Reliner Producing Co., Lima, Ohio, is preparing to increase the national and international orders and double the amount of its working force.

Hare's Motors, Inc., announces the removal of its executive offices to the Canadian Pacific Building, New York City.

The American Forge Co., Chicago, has changed its corporate name to the AmForge Co.

## DODGE GETS WINDSOR PLANT

WINDSOR, ONT., Oct. 5—Dodge Bros. Motor Car Co. of Detroit has leased a wharf and building from the Canadian Pacific Railway in Windsor, Ont., and is assembling cars there. It is understood that a Canadian company is being incorporated and the location of an automobile factory in Canada is probable.

## Farmers Opposing Reimportation Tax

### Possibility That Graham Measure May Be Defeated Though Senate Bloc

WASHINGTON, Oct. 4—Opposition to the so-called Graham Resolution, which would impose a tax of 90 per cent on re-importations of surplus war supplies, including motor trucks and automobiles, has been expressed by the Oklahoma Farmers Union and the State Farm Bureau Federation. The resolution is now pending on the Senate calendar owing to the fact that objection by Senator Pomerene and others prevented its passage before the summer recess of Congress.

It is the contention of the Farm Bureau Federation that many concerns importing automobiles have contracted to deliver to the farmers automobiles at \$500 each which now sell in this country for \$1,100 or more, and this purchase price includes ocean freight and commission. The organized farmers insist that they can obtain motorized equipment for their farms at a saving of 50 per cent of the wholesale price by purchasing the reimported goods. As a consequence, they are against the Graham Resolution, which would protect the motor truck manufacturers and dealers in this country from this form of foreign competition. If other farm organizations join with these two groups, it is barely possible that the so-called agricultural bloc in the Senate will defeat the Graham measure.

The prospect of delay in the enactment of the Graham bill is particularly disturbing at this time to dealers who have felt the effects of this competition. The Graham measure was designed to provide protection during the time the tariff bill was under discussion. There is a measure in the House tariff bill which provides for assessment of heavy duties on re-imported war materials. It was incorporated in the bill because of the country-wide agitation conducted by organized automobile dealers and manufacturers.

### Poughkeepsie Factory of Fiat on Market

NEW YORK, Oct. 5—The factory at Poughkeepsie formerly used by the Fiat Automobile Co. has been placed on the market by individuals who now own it. The plant originally was used for the assembling of Fiat cars. Most of the parts were imported from the parent factory at Turin, Italy, but some of them were obtained in this country. With the outbreak of the war importation of parts became impossible and the assembling of cars ceased. The Fiat company now is importing complete cars. The parent company is not directly interested in the Poughkeepsie plant.

## September Shipments Show Slight Decrease

NEW YORK, Oct. 5.—Reports of September shipments of cars and trucks made to the National Automobile Chamber of Commerce by its members show that there was a decrease of 4 per cent as compared with last month, but they totaled 85 per cent of September, 1920. In the same month last year shipments were 16½ per cent less than in August. The September shipments compare more favorably with the same month last year than those of any previous month for 1921. The shipment figures by months for this year and last follow:

	Carloads		Driveaways		Boat	
	1920	1921	1920	1921	1920	1921
January .....	25,057	6,485	29,283	3,185	....	93
February .....	25,505	9,986	43,719	7,507	....	99
March .....	29,326	16,287	57,273	9,939	....	75
April .....	17,147	20,187	64,634	14,197	....	1,619
May .....	21,977	18,608	74,286	15,193	....	2,381
June .....	22,516	20,269	60,746	18,834	8,350	3,947
July .....	23,082	19,470	52,342	15,320	8,702	3,725
August .....	23,386	20,350	34,060	14,290	7,095	3,565
September .....	20,804	20,150	24,431	13,550	5,469	3,580

### Branches Supplant Two Studebaker Distributors

CLEVELAND, Oct. 4—George E. Willis, who has been in charge of the Studebaker's export business and but recently returned from a trip to Germany and Russia, has become head of the Studebaker distributing agency in the Cleveland district, succeeding Aaron Du Roy and Joseph O. Hahn in the active management of the Studebaker Sales Co. The following officers were elected at a meeting of the directors: A. R. Erskine, president; H. A. Briggs, vice-president; George E. Willis, general manager; F. C. Kenny, treasurer, and A. G. Rumpf, secretary. Regarding plans, Willis says, "Aside from the change in officers, the Studebaker Sales Co. of Ohio will be conducted along the same lines as heretofore. Eventually it is the intention of the Studebaker corporation to establish a direct factory branch in this city and to liquidate the Studebaker sales company."

PITTSBURGH, Oct. 4—According to Aaron Du Roy, he and Joseph O. Hahn have sold their entire holdings in the Studebaker Sales Co. to the Studebaker Corp. of America. Du Roy has handled the Studebaker line in the western Pennsylvania territory since 1909. He and Hahn formed the sales company five years ago and handled the Studebaker in the State of Ohio, western Pennsylvania and part of West Virginia, the Studebaker corporation being interested in the company. The B. F. Stout building has been leased for a long term of years to house the factory branch which will supplant the sales company.

### PRIZE FOR BEST AIR MOTOR

NEW YORK, Oct. 4—A dispatch from Paris says the French committee for aeronautic propaganda has decided to create a prize of one million francs for the commercial aviation motor which best satisfies tests, in a competition to be arranged, in point of durability, regularity, simplicity, dismounting and in regard to upkeep.

### Snead Vice-President, H. P. Macdonald, Dies

JERSEY CITY, Oct. 5—The death is announced of H. P. Macdonald, a vice-president of Snead & Co., manufacturers of Snead cushion drives. He was born in Louisville, Ky., in 1880 and was graduated from the Massachusetts Institute of Technology in 1901. He went with Snead & Co. the same year, serving successively as assistant superintendent, general superintendent, chief engineer and vice-president. He was a member of the Society of Automotive Engineers and several other engineering societies.

Macdonald was responsible for a series of inventions relative to the electrical heat treating of ferrous and non-ferrous metals by means of internal resistance. This system was used extensively during the war for the heat treating of steel tubing for airplanes made by the Allies.

Edward M. Huggins, formerly assistant chief engineer of Snead & Co., has been promoted to chief engineer and Ira S. Snead, general sales manager, has been elected to the office of vice-president left vacant by the death of Macdonald.

### Suggests Dealers Get Rediscount Rate Data

WASHINGTON, Oct. 5—Suggestion has been made by Governor Harding of the Federal Reserve Board that automobile dealers in the principal cities inquire of their banks as to what the effect of lower rediscount rates at Federal Reserve banks would be on rates of interest charged by local member banks and then furnish the board with a synopsis of findings. This data will be used by the Federal Reserve Board Advisory Council, which is a statutory body authorized to make recommendations in regard to discount and rediscount rates. Their recommendations had much to do with tightening up credit on automobile dealers and manufacturers in the spring of 1920.

Indications are that the banks will bring about changes to ease the credit situation.

## Seiberling States Plans For Future

### Crisis in Past Came Because of Failure to Anticipate Reaction

CLEVELAND, Oct. 4.—Frank A. Seiberling of Akron, who built the Goodyear Tire & Rubber Co. from a puny corporation to the leading concern of its kind in the world, and who at 61 is now starting to build up another gigantic business, came to Cleveland last week and gave to *Finance and Industry*, a business paper, his plans for his industrial regeneration.

True, Seiberling has aged considerably since the day he borrowed the capital to start the Goodyear plant, but he is just as full of initiative, optimism and fight as he was when he made the initial endeavor.

Although his new start upward is just in its infancy, he already has practically acquired plants which will provide 5000 casings and 6000 inner tubes daily. In the closing days of his career at the Goodyear plant he was expanding production by building new plants and factory additions when the market for raw materials and finished products was at the peak. He did so because the market was at his heels daily, demanding more and more tires.

#### Tells of Collapse

The crisis came to him, he says, because of a failure to anticipate the day and the hour when the reaction would come. Continuing about his collapse at the Goodyear plant, Seiberling says:

"We all sensed the coming crisis; but no one saw it. The business was expanding rapidly. Why, in the first half of 1920 we were in volume of business, 50 per cent ahead of the first six months in 1919. Manufacturers were tramping on our heels to get tires. We tried to keep pace with the requirements of the trade of our old customers. Demand kept mounting; no one foresaw the precise moment when it would end. Well, it arrived. We tried to get money to help us past the crisis in anticipation of a broader program of financing. We found that it was impossible to do any long time financing in the latter part of 1920. We were forced to temporary financing. The purpose of such financing was to save the community of Akron and the cotton mills and other interests with whom we had contracts from the calamity of a receivership for Goodyear. I did not want the responsibility for forcing the cotton mills into bankruptcy placed on Goodyear. We made the best terms that we could and saved the company. I went thru with that bargain to the last. Officially I got out of Goodyear on Friday May 13. I stayed on two weeks longer to clear up certain matters. I gave all the assistance I could, because—well you see—I nursed Goodyear up from nothing to leadership in its line—and it meant something to me."

In the last days of his leadership of Goodyear, Seiberling was expanding and building up his factories at the fag end of a boom period. Now we see him in a different rôle. He has started out to

buy when others are out of the market. That means low prices for the factories.

Here's a quotation on this point from Seiberling: "The year 1922 will see wonders performed in improving processes and perfecting units. It is apparent that by taking old plants at low valuations, the obsolescence will have been charged off. With these plants I will be contented for the present. Some day I hope to build the most efficient rubber plant in the world."

There's plenty of cheer in this statement by Seiberling: "We are on the eve of startling developments, both chemically and mechanically, in the tire business. These developments will be of great value to the tire business and the public, for they will reduce the cost of operating cars on pneumatic tires."

#### Country on Economic Basis

The speaker asserted that he and his brother, C. W. Seiberling, are re-engaging in the rubber business for two reasons: First, because it is the business they know and, second, it offers the best future opportunities. Seiberling then reviews the boom times of the war and the abnormal demand that brought great expansion. Now, he says, the country is getting down to an economic equilibrium. He predicts that the number of automobiles and trucks in use will grow next year from 9,000,000 to 10,000,000 and that it will steadily increase to 15,000,000.

He says that the growth in the number of automobiles does not mean that the tire industry is to grow in units in the same proportion.

"On the contrary," he states, "the development in the tire industry is likely to be in the quality of the product—increasing the mileage of tires. By that I mean a reduction in the cost per mile run; so that the number of tires produced may increase very little over the number heretofore turned out."

"We have acquired a plant at New Castle and have made an offer for the Portage Rubber Co., near Akron. With these two plants we would have a capacity of 5000 casings and 6000 tubes a day. I am proposing to take over the Portage plant for \$750,000. It will be paid in preferred stock of a corporation to be organized to own that plant. The common stock of the Portage plant will go to a holding company that I am organizing for operating purposes. The holding company will own the New Castle plant in fee, having paid for it in common stock at its present appraised value. Later I plan to offer securities to the public to the extent necessary to cover requirements of working capital."

#### GEORGIA RAILROAD SUFFERS

ATLANTA, Oct. 3.—Automobile truck competition may force the Gainesville Midland Railroad of Georgia into the scrap pile, according to a recent letter to a newspaper at Athens, Ga. written by W. B. Veazy, receiver for the road. The territory in northeast Georgia served by the railroad produces ample business to make it pay, but the extensive use of the motor trucks for inter-city transportation in that section, Veazy states, is slowly ruining the business of the railroad.

## Tests Aid Sales in South Africa

### Spring Season Now Realized As Time for Excellent Business Possibilities

JOHANNESBURG, Sept. 15. (*By Mail*)—The month of August saw the finish of the Transvaal Automobile Club Reliability Trials from Johannesburg to Durban. The start was made on July 30 and the trials extended over three days. The distance to Durban is 410 miles and the roads passed over were in varying states of repair. Altogether the trials have done a great deal for the cause of motoring in South Africa. A Buick Six, driven by A. Williams, General Motors representative, took first place in the professional class and was awarded 197.6 marks out of a possible 200. The weight of the car was slightly over 2½ tons loaded and the gasoline consumption 23.45 m.p.g. A Talbot was placed second, with a Scripps-Booth third.

As an aftermath to these tests several attempts were made to lower the road record from Durban to Johannesburg. In its class the Hupmobile stands first at 14 hours 41½ minutes for the distance of 410 miles. The difference in altitude between Durban and Johannesburg is 6000 feet. The Chevrolet holds the best time for its class with 15 hours 21 minutes to its credit. A Nash stock model was driven from Pretoria to Durban and back without a stop, a distance of 892 miles, in 36 hours.

#### Further Cuts Expected

The cause of transportation has received impetus from the different events mentioned above and dealers are making preparations to capture as much of the spring trade as possible. On account of the genial climate that prevails in South Africa dealers have not made spring a special season for sales, but they have realized that it is a season when much excellent business can be done.

Still further price cuts have been notified by some of the tire companies and gasoline has come down in price, no less than two reductions being made recently. The reduction of running costs will help the dealers with sales this year, as running costs have been a bar to a number of sales during the past twelve months. Car prices appear to be stable for a time now, but buyers have been nervous of late on account of further price cuts being expected by them. Dealers, however, are advising the public that prices will remain on the present level for some time.

English cars and trucks are entering the market and creating competition. The Wolsley cars and Leyland trucks are being extensively placed throughout the country. Wolsley are building special colonial models for this country and the Leyland people are adapting their trucks to suit conditions here.

## MEN OF THE INDUSTRY

**William M. Sweet**, a director and vice-president of The Klaxon Co., has relinquished his other duties with the General Motors Corp. to devote his entire attention to the Klaxon interests as vice-president. From 1907 to 1916 Sweet was general manager of the M. A. M. A., resigning to become assistant to A. P. Sloan, Jr., president of the United Motors Corp.; later also becoming assistant secretary and assistant treasurer. In 1918, when United Motors was consolidated with General Motors Corp., Sloan became vice-president of the latter corporation and Sweet continued as his assistant, later becoming assistant secretary of the corporation. Sweet is a vice-president, director and member of the executive committee of Bearings Service Co. Since 1910 he has also been a director and member of the executive committee of the A. A. A., and during the past five years has been vice-president of the Metropolitan Council of that association.

**Murry Irwin** has been elected president of the Advance Manufacturing & Tool Co., making screw machine products and automobile parts in its plant in Cleveland. R. H. Lord has been chosen secretary and treasurer. The other two directors of the corporation are Joseph G. Fogg, former president, and H. W. Sissen, both of whom are lawyers. Irwin, before coming to Cleveland, was sales manager for the Lewis Spring & Axle Co. at Jackson and general manager for the Adams Axle Co. at Findlay, Ohio. The Advance company was incorporated with a capital of \$200,000 and all of the stock has been sold. It has been in production in Cleveland for three years.

**A. M. Leonl**, who brought the P-T tractor wheel to this country from Italy some years ago and who later designed the 3-4 plow Tloga farm tractor, has secured an option on the American patents on the Pavest road and farm tractor, which was described in AUTOMOTIVE INDUSTRIES of Dec. 18, 1919, and Jan. 1, 1920. Mr. Leonl plans to produce a machine specially suited to orchard work and rice cultivation.

**H. J. Edwards** has been appointed supervisor of the Detroit district for the Maxwell Motor Sales Corp. and the Chalmers Motor Car Co. Edwards was connected for many years with the Union Carbide & Carbon Co., both as sales manager and as general manager of several of their subsidiaries, notably the Prestolite Co. Prior to that he was eastern manager for the Moline Plow Co.

**Fritz R. Lindh**, formerly chief engineer of the Graton & Knight Mfg. Co., in which capacity he was in charge of all field research and testing at the factory as well as all field engineering service, has joined the sales organization of the Chicago Belting Co. He will be in charge of the Pittsburgh direct factory branch with headquarters in that city.

**Chas. E. Wagner** has joined the sales staff of the Maxwell Motor Sales Corp. and the Chalmers Motor Car Co. Wagner has been with the Willys-Overland Co. for the past nine years, serving in many capacities ranging from that of factory representative to distributor.

**H. R. Sturgeon**, who was connected with the John N. Willys Export Corp. as advertising manager and previously had been in the advertising department of the Willys-Overland Co. at Toledo, is now associated with the John O. Munn Co. as vice-president.

**H. R. Averill** has become associated with the Cole Motor Car Co., Indianapolis, in the capacity of special representative. Averill

has spent twenty odd years in the automotive industry and was recently identified with the National.

**E. E. Aldous**, for twenty-seven years connected with the American Steel & Wire Co., Chicago, has been named the company's representative in the St. Paul-Minneapolis-Duluth territory with headquarters at St. Paul.

**Curtis W. Keegin** has been appointed by the Cincinnati Ball Crank Co. as district manager for Michigan. Keegin was formerly with the Hyatt Roller Bearing Co. and Continental Motors Corp.

**George C. McMullen**, formerly Pacific coast representative of the Timken Roller Bearing Co., industrial division, has been placed in charge of the division.

## BANK CREDITS

*Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.*

Last week's statement of condition of the Federal Reserve Banks showed a continuation of the improvement in the reserve ratio which has been unbroken since early in July, with the exception of the first week in September. Gold reserves increased \$14,338,000 from the figure of the previous week, total reserves increasing \$15,589,000 to \$2,878,685,000. Deposits increased \$25,795,000, while Federal Reserve notes in actual circulation declined \$17,480,000. The ratio of total reserves to deposit and Federal Reserve note liabilities combined rose, accordingly, from 68.7 per cent to 69 per cent. Total bills on hand increased \$21,041,000, as compared with a decline of \$48,123,000 in the previous week.

There were no striking developments in the local money market last week. The range of rates on call loans was from 5 per cent to 6 per cent, compared with 4½ per cent to 5½ per cent the previous week. The higher range may be attributed to preparations for the usual month-end settlements. Outside the Stock Exchange loans were made at 4½ per cent. Quotations for time money remained unchanged, with only a light volume of transactions effected. Corresponding stability was shown in the market for commercial paper.

The Government report of the condition of the cotton crop as of Sept. 25 established a new low record of 42.2 per cent. The new indicated yield is 6,537,000 bales, representing a reduction in estimated yield of 500,000 bales from the estimate of Aug. 25. It is evident that approximately normal consumption in the next twelve months would draw heavily upon the large carry-over from last season.

The number of commercial failures in the United States in September, as reported by *The Credit Guide*, declined about 5 per cent compared with failures in August. Average liabilities also declined. The volume of bank clearings last week was substantially greater than in the previous week. These figures are indicative of the rather general improvement in trade which has been under way for some weeks.

N.A.C.C. Considers  
Problems of DealersUsed Car Question and Finances  
Held Most Important in  
Discussions

NEW YORK, Oct. 6—Problems of vital concern to the automobile dealer were considered by the directors of the National Automobile Chamber of Commerce at their monthly meeting yesterday and the discussion was continued at the annual members' meeting to-day. Solution of the used car question was considered of most importance and bearing directly on this was the subject of dealer finances. It was contended that manufacturers are taking their losses on their inventories and that dealers are taking theirs on used cars.

Reports received from all sections of the country on business conditions indicated that trade is best in the East and South but that truck sales are improving in Nebraska, Missouri and New York. There still is a scarcity of credit for dealers.

Five more applications than last year were received for space in the New York show. Space was drawn this afternoon. All the applicants will be taken care of in this city but it probably will be necessary to leave a few out of the Chicago exposition.

**J. A. Haskell**, vice-president of the General Motors Corp., was elected a director to succeed W. C. Sills.

Durant Motors of New York was elected to membership in the chamber.

A report on tire standardization, accepted by the Society of Automotive Engineers and the Rubber Association of America, was submitted.

## DUER NAMED RECEIVER

NEW YORK, Oct. 6—Edward R. Duer has been appointed receiver for the Rubber Corp. of America in an action filed by the Equitable Trust Co. which holds a note for \$70,000. Liabilities are listed at about \$900,000 and the assets are approximately \$1,030,000. It was said that the object of the receivership was to conserve the assets of the company so that it either could be liquidated or reorganized in conjunction with the Empire Tire & Rubber Co. of Trenton.

## BURT, REPUBLIC DIRECTOR

NEW YORK, Oct. 6—At the annual meeting of stockholders of the Republic Motor Truck Co., Inc., the only change made in the directorate was occasioned by the resignation of A. H. Ide of Troy, N. Y., and the election in his place of T. A. Burt of Urbana, Ill., who will represent large holdings of Republic stock in the Chicago district.

## PETITION AGAINST WAYNE

DETROIT, Oct. 6—An involuntary petition in bankruptcy has been filed in Federal Court against the Wayne Tractor Co. by creditors.

## METAL MARKETS

**W**HILE minor price changes in the steel market are a probability rather than a possibility, the consensus of opinion in conservative quarters is that no radical making over of values will take place during the last quarter of the year. There are those who see in the rate of operations which has been attained by sheet mills justification for further advances, but the sentiment among representative producers of a diversified line of steel products (for many of which there is still very little demand) is to let well enough alone. If the smaller sheet mills, many of which are dependent upon other producers for their supply of sheet bars, should succeed in elevating the sheet market further, they will be called upon to pay proportionately increased prices for sheet bars, so that in the end they would not be so much the gainers. Moreover, advances in the case of many steel products imply advances in the wages of operatives, which are based on a sliding scale figured on the preceding month's average sales levels. Such advances are hardly conducive to what adjustment remains to be made in the matter of wage schedules generally. In spite of the insistent demands for immediate downward revision of freight rates, there is little likelihood of worthwhile results being achieved during the remainder of the year. The fact is altogether too frequently overlooked that the slight rebounds which have taken place of late in steel prices were not so much due to the enhanced demand as to the fact that deflation in the pig iron and steel markets was based on anticipation of at least partial deflation of freight rates and fuel prices and, when these failed to materialize after a reasonable length of time, the slightest revival of demand was bound to result in a recoil of prices. Automotive interests have been consistent in their attitude toward the market in the last few months and continue to be so, refusing to commit themselves beyond the tonnages which their operating schedules call for. While the desire to avoid carrying a large amount of raw material undoubtedly accounts in a large measure for this attitude, this policy also appears to be the most sagacious one to follow amid the present conditions in the steel market.

**Pig iron.**—Although pig iron interests continue to nurse assiduously the "little boom," as they call the return of more representative buying and further advances are prognosticated, restraint is being more and more imposed by increased production, a number of furnaces heretofore idle preparing to resume operations. Automotive foundries display slight interest in offerings and are not perturbed by the avowed unwillingness of furnace representatives to book orders for deferred shipment.

**Steel.**—"Independents" have advanced their price for sheet bars to \$32.50, which affects chiefly non-integrated sheet makers. The Corporation's sheet bar price is nominally \$35. Some of the Youngstown district sheet mills, flushed by the return of 66% to 75 per cent operations, are obtaining a bonus of \$1 to \$2 a ton for immediate deliveries, overnight shipments, which they were only too glad to make a few weeks ago, having disappeared. Automobile body makers still have considerable tonnages of sheets coming to them at prices below the present market. Demand for No. 22 gage full finished body sheets has eased off, the market remaining notably unchanged at 4.35c. Pittsburgh. Cold-drawn steel bars are in fair demand by passenger car builders, but only small lots

are wanted. The same is true of cold-rolled strip steel. Bolts and nuts are in routine inquiry with prices rather flexible.

**Aluminum.**—The market continues weak and entirely in buyers' favor.

**Copper.**—Domestic consuming demand has improved and, in addition, producers are supporting the market, weaker holders of resale lots having previously liquidated their stocks.

**Tin.**—Primary markets display more optimism, which London encourages.

**Lead.**—The market continues steady, with battery makers buying somewhat more freely.

**Zinc.**—Fair demand for galvanizing purposes is noted. Brass mills still have large tonnages of scrap to fall back upon.

## FINANCIAL NOTES

**Ford Motor Co. of Canada** did business to the amount of \$37,836,473.40 in the year ending July 31, 1921, according to Gordon M. McGregor, vice-president and general manager. After provision had been made for all expenses and for income tax the net profits transferred to the surplus of the company were \$2,121,501.11, in addition to which should be added \$231,127.96, balance remaining in the 1920 business profits tax reserve. Total assets are given as \$18,835,405.69. The output for the year was 46,832 automobiles and 3063 tractors, compared with 55,616 cars and 2335 tractors for the year previous.

**Kelly-Springfield Tire Co.** declared the regular quarterly dividend of 3 per cent on the common stock, payable Nov. 1 to stock of record Oct. 14. Regular quarterly dividend of 2 per cent on the 8 per cent preferred stock also has been declared, payable Nov. 15 to stock of record Nov. 1.

**Erie Tire & Rubber Co., Sandusky,** is solvent with assets of \$800,000 in excess of liabilities, according to a complete audit of the company's affairs from its inception until June 30 of this year, filed by Receiver H. R. Greenlee.

**Moon Motor Car Co.** board of directors has declared the regular quarterly dividend of 1% per cent on preferred stock outstanding, payable Oct. 1.

**Hupp Motor Car Co.** has declared the regular quarterly dividend of 2½ per cent on the common stock, payable Nov. 1 to stock of record Oct. 15.

**Fisher Body Co. of Ohio** has declared the regular quarterly dividend of \$2 on the preferred stock, payable Oct. 11 to stock of record Oct. 4.

Stockholders Approve  
Sunnyhome Dissolution

**NEW YORK, Oct. 5**—Stockholders of the Sunnyhome Electric Co., one of the units of the United Motors group of the General Motors Corp., have approved a resolution to dissolve the company. Claims must be filed by Oct. 19.

General Motors Corp. denied last May that it proposed to sell the Frigidaire Corp., the Sunnyhome Electric Co. and other units not directly connected with automotive products. It was stated then that the sale of the Frigidaire refrigerator would be extended through the sales organization of the Delco Light Co. and that the Sunnyhome company would be consolidated with the Delco company. The dissolution of Sunnyhome is the final step in the consolidation.

Trade to Far East  
Is Well Under Way

## Orient and Latin-America Markets Held Most Important in Foreign Field

**NEW YORK, Oct. 4**—That the Far East and Latin-American markets were the most important in the foreign field was the consensus of opinion expressed here to-day by export managers of the National Automobile Chamber of Commerce at the first monthly luncheon of the present season. The meeting to-day was called especially to introduce William I. Irvine, trade commissioner of the automotive division of the Bureau of Foreign and Domestic Commerce, to the local exporters.

Irvine, after outlining the work the new division hopes to perform and asking the co-operation of the automotive companies, requested the opinion of the members as to which markets should receive particular attention at this time and which likewise could be counted as offering the greatest potential trade for the American companies. Both the Orient and Latin-America were suggested by the exporters present, some of them stating that Latin-America was the more important at this time while others stood out for the Far East. All were positive, however, that these sections should receive careful attention and that sales efforts should not be slackened the slightest. That conditions were improving in each territory and that a resumption of business on a larger scale was imminent was the apparent belief of each speaker.

Irvine plans to leave Washington shortly after the new year on an investigating trip throughout the world.

To Buy Portage Plant  
with Preferred Stock

**AKRON, Oct. 5**—F. A. Seiberling, who will purchase the plant and equipment of the Portage Rubber Co. of Barberton, Ohio, for \$750,000, announces that payment will be made in preferred stock of the corporation which is to be organized. The common stock of the Portage company will go to a holding company which is being formed for operating purposes. The holding company also will own the plant of the New Castle Rubber Co.

It is proposed later to offer certificates to the public to the extent necessary to cover working capital requirements. The two plants have a combined capacity of about 5000 casings and 6000 tubes daily.

## U. S. TRUCK DIVIDEND

**CINCINNATI, Oct. 6**—The United States Motor Truck Co. has declared its regular quarterly dividend of 1% per cent. The company reports that in the first four days of October it booked and had on hand more unfilled orders than in any like period in the past eight months.

# Calendar

## SHOWS

Sept. 28 - Oct. 8—New York, Electrical Exposition, 71st Regt. Armory, Electric Equipment, Machinery and Vehicles.

Nov. 14-19—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association, Fourth Regiment Armory.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Grand Central Palace, Auspices of N.A.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.A.C.C.

Feb. 6 to 11—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.

Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Oct. 10-22—Olympia, England, Truck Show. Nov. 4-12—Car Show. Nov. 28-Dec. 3—Motorcycle Show.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

November 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.

Nov. 26 - Dec. 3—Shanghai, China, Automobile Show.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibits in connection with the Brazilian Centenary Association Automobilista Brasileira.

## CONVENTIONS

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Nov. 15-17—Kansas City, Second Annual Meeting of American Petroleum Institute.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

Jan. 17-20, 1922—Chicago, American Road Builders Association.

## S. A. E. MEETINGS

Detroit, Oct. 21, Nov. 13, Dec. 23, Feb. 24, March 24, April 28, May 26.

New York, Jan. 10-13, 1922—Annual Meeting.

## Northwest Analysis Puts Wyoming First

### Percentage of Increased Car Registrations in That State Slightly Exceeds Oregon

PORTLAND, ORE., Sept. 30—If a comparison of the rate of increase in the use of motor vehicles may serve as a criterion the State of Oregon is at present enjoying a greater degree of prosperity than any other State of the Pacific Northwest, excepting Wyoming, according to Sam Kozar, secretary of state for Oregon, who has made public figures which he obtained through a sweeping analysis of the situation in Arizona, Colorado, Idaho, Montana, Nevada, Oregon, Utah, Washington and Wyoming.

"Registration of motor vehicles in Oregon for the first seven months of 1921 show a greater percentage of increase in comparison with the total registrations during the year 1920 than is shown by the available official records of any other western state except Wyoming, and eliminating California, for which similar records are not available," said Kozar.

Such a comparison shows, his report indicates, that during the first seven months of 1921 there were registered in Oregon 105.3 per cent of the number of cars registered during the entire previous year of 1920. Figures for the other States show the following percentages: Arizona 95.24 per cent, Idaho 93.58 per cent, Montana 89.61 per cent, Utah 100.84 per cent, Washington 90.63 per cent, Colorado 96.4 per cent, Nevada 99.05 per cent and Wyoming 105.75 per cent. The last three mentioned States have provided figures only to cover the first six months of 1921 and thus would make a slightly better showing if July, 1921, registrations were also included.

A study of motor vehicle registrations in proportion to population, also made by Kozar, shows that in this regard

Washington is in the lead among the far western States, excluding California, for which statistics are not available for such a comparison, while Oregon is third. Giving his figures on this feature of his study Kozar says:

"Official figures received from eight other western states show that during the first seven months of 1921 Arizona registered one motor vehicle to every 9.67 persons, Colorado one for every 7.27 persons, Idaho one to every 8.49, Montana one to every 9.05, Nevada one to every 7.39, Oregon one to every 7.54, Utah one to every 10.56, Washington one to every 7.14 and Wyoming one to every 8.6 persons. The states mentioned thus rank in the following order in ratio of motor vehicles to total populations: Washington, Colorado, Oregon, Idaho, Wyoming, Montana, Arizona, Utah."

## Twenty-three Makes for Commodore Salon

NEW YORK, Sept. 30—Twenty-three makes of American and foreign high grade cars will be exhibited at the automobile salon which will be held at the Hotel Commodore, this city, from Nov. 27 to Dec. 3 and at the Drake Hotel, Chicago, coincident with the National Automobile Show there the latter part of January. There will also be ten custom body builders. Because of the demand for space cars will be exhibited in the lobby and on the mezzanine balcony of the Commodore as well as on the entire second floor.

## COVENTRY MAKES NO RETURN

LONDON, Sept. 16 (By Mail)—The receiver and manager of the Coventry Premier (Limited) since it went into involuntary liquidation has issued a notice to the stockholders pointing out that the proceeds are insufficient to repay the debentures in full, so that there will be no return to either class of shareholders. The company's assets were absorbed by the Singer interests in Coventry. The latter's output is a light car and its report recently issued shows a good return on the capital.

## Kansas City Shows Accessories Gain

### Cars Also in Demand—Commodities with Recognized Name Have Largest Demand

KANSAS CITY, Sept. 30—The upturn in the automotive industry of this territory is reflected in the monthly bulletin of the Federal Reserve Bank, which shows a gain of about 16 per cent in distribution of accessories in August, over July. There is still a deficiency of more than that amount from the distribution of August, 1920, partly taken up in decline in prices. September, judging from casual reports, is showing a marked increase over August, in both accessories and cars. One distributor reported the best August business in his branch's history; and many distributors are having good success, while retailers are in some cases having larger volume in cars than ever before.

The distributors and dealers who are enjoying the largest business are those with established plants here, handling well known cars, whose prices, whether high or low, have been readjusted. Expensive cars seem to be selling proportionately as well as less expensive cars.

From many diverse quarters, the report comes that commodities having the benefit of public or trade knowledge of the name and quality are being asked for. Clothiers, for instance, are turning to brands which they are sure of, through their long acquaintance with names and reputations.

## INDIANA TRUCK DISSOLVED

MARION, IND., Sept. 30—The Indiana Truck Corp. has wound up the affairs of the Indiana Truck Co. which it succeeded with the same management. The company dissolved was incorporated in 1906 and was succeeded by the present company in 1916.

Continental achievements in the past have earned the whole-hearted CONFIDENCE of the motor using public. And, in a like manner, Continental co-operation in transportation undertakings has resulted in the complete CONFIDENCE of the automotive industry. ¶ This broadcast CONFIDENCE is gratifying, but it is not accepted by the Continental organization as a mere reward granted for past performances. It is accepted rather as a well defined obli-

gation to strive for even greater achievements in the future. ¶ It is to be expected, therefore, that the product whose manufacture is characterized by such a spirit, will operate with unique precision—precision that unavoidably creates the impression that the motor, itself, possesses CONFIDENCE in its own ability—precision that is bound to enhance universal respect for that well known symbol of excellence—the Continental Red Seal.

## Trend to Light Cars and Fuel Economy in Paris Show

Engineering efforts to give greater economy of operation are in evidence, but price reductions are few. 4-cylinder models predominate to a greater extent. Three-speed transmissions extensively used on more powerful cars. Only two English cars shown.

By W. F. Bradley

PARIS, Oct. 8.  
**T**HE Paris automobile show, the second held since the Armistice, was officially opened to the public by the Minister of Public Works in the Grand Palais, on Wednesday last, with a record number of exhibitors representative of the entire French automobile and accessory industries. The names of 830 exhibitors are given in the list and of these about 80 per cent are French. Owing to the great demand for space, it was necessary to erect a special building for trucks and tractors. Only two English cars were shown. The American industry is represented by the Pierce-Arrow, Cadillac, Standard and Buick. Practically all of the Italian makers are showing their products.

These figures indicate that the Paris show, like the Berlin show, was largely national in character. No attempt at the exclusion of foreign cars was made, of course, as in the case of the German show, except that German manufacturers were prohibited from exhibiting. The small number of British exhibitors indicates that the Britons will be content with concentrating their efforts on the Olympia show. Thus the Italians are the only foreign makers to exhibit as a body. This is probably due to the very poor

home market which has faced the Italian makers during the last few years.

French manufacturers insist that the present high taxes on gasoline are a large factor in retarding the trade. These taxes, together with the high import duties which France has placed upon foreign cars, are doubtless responsible to a large extent for the decline in the international flavor of the Paris salon. The American makers have evinced considerable interest in the show, nevertheless, since they outnumber the British exhibitors, despite the fact that they have extremely unfavorable exchange conditions in addition to the other difficulties presented.

French manufacturers are hopeful that the show will mark the end of the industrial depression. It is believed in some quarters that the wish is largely father to the thought so far as this is concerned. The past 18 months have been so disastrous that even the most optimistic are merely hopeful rather than assured. The factors underlying the depression are such, however, as to indicate that the show itself can have little more than a helpful influence on the condition of the industry. As noted previously, the manufacturers believe the high gasoline taxes to be responsible for a large measure of sales resistance,

while other factors of similar nature have served to make marketing difficult.

There is a definite feeling, however, among those closely in touch with the situation that a real buying campaign may set in following the salon. This feeling is based upon an observation of the visitors to the show and of the live interest which has been shown in many of the exhibits. Aside from the hindrances to selling mentioned, there has been something of a general disinclination to buy, similar to that experienced in the United States. The interest stimulated by the salon is expected to have a very favorable effect in overcoming this attitude, and there are already some indications, after the first few days of the show, that these expectations will be fulfilled to some extent.

French manufacturers are hopeful that the show will mark the end of the industrial depression, but the past 18 months have been so disastrous that it is more a case of hopefulness than of assurance. The impression prevails, however, that, after the first few days of the show a real buying campaign will set in. Manufacturers insist that if the government would remove the present high taxes on gasoline a great impetus would be given to trade.

In a technical way, much effort has been made by the French industry to attract buyers. In view of the fact that the public desires greater economy of operation, practically all makers are producing smaller and lighter designs. The dominating type at the show is a light, 4-passenger, 4-cylinder car of 120 cu. in. piston displacement or less, with a nominal rating of 10 horsepower. Some of the firms which have always been catering to the high-class trade and never previously have built cars of this type, have entered this class. Panhard, for instance, offers a 4-cylinder Knight engined car of 60 x 105 mm. cylinder dimensions (2.36 x 4.13 in.). Voisin also shows a 4-cylinder Knight engined car of 60 x 110 mm. cylinder dimensions (2.36 x 4.33). Darracq, Delage, Delaunay-Belleville, Delahaye and Chenard-Walcker are other firms building smaller cars than they have ever turned out before. Citroen, while continuing his present model, has placed on the market a 5-hp. 2-seater with a 4-cylinder 55 x 90 mm (2.16 x 3.54 in.) engine, which sells complete for 8500 francs (\$653 on the basis of the current rate of exchange). For the manufacture of this car Voisin has secured control of the Clement-Bayard factory.

Very few reductions in price have been announced, the makers declaring that rock bottom figures have been reached, and it is believed that competition is causing some of the smaller makers to sell below manufacturing cost. The price of the Citroen 4-seater is now 13,900 francs (\$1,000).

Talbot-Darracq has put out a 12-hp. 5-passenger car at 22,000 francs (\$1,585), this being one of the cheapest 6-cylinder models shown. The Lorraine-Dietrich 6-passenger sells at 28,750 francs (\$2,075). Fiat has reduced the price on the 10-hp. 4-passenger model to 21,500 francs (\$1,550).

Four-cylinder models are in a greater majority than at any time in recent years and are followed by the 6-cylinders. Only two 12-cylinder models are being exhibited, a luxury type Voisin 12 with an all-aluminum

engine of the Knight sleeve-valve type and a Fiat 12 with overhead valves and the camshaft in the crank chamber. Lancia, another Italian maker, is showing an 8-cylinder chassis which has the peculiarity that the two cylinder blocks of the V-engine make an angle of only 14 deg. with each other. Bugatti, who claims to have been the first to have turned out an 8-cylinder in-line engine, of 3 litres (183 cu. in.) piston displacement, is showing a sport model of this type. Panhard is showing a new 8-cylinder in-line Knight-engined car and Fonck also shows an 8-cylinder in-line model. No other multi-cylinder engines have made their appearance. Ballot is marketing duplicates of his 2 litre (122 cu. in.) racing jobs with sport bodies.

The most outstanding feature of the show is the use of front wheel brakes by 35 different firms, 23 of which are working under Perrot license. Bugatti, Rolland-Pilain and Voisin are using hydraulically operated brakes, while on the Slim car compressed air is used for applying the front brakes. Among the important firms which have recently adopted front-wheel brakes may be mentioned Panhard, Fiat, Hotchkiss, Rochet-Schneider and Farman. There are several instances in which front brakes are fitted to chassis with a rating of 15 hp.

or less, and buyers in a great many cases now insist on these brakes. Servo brakes, by which is meant brakes which are operated by other than muscular energy, are used on several cars, including the Ballot, Panhard, Bignan and Chenard-Walcker. The Mallot servo brake, with which it is impossible to lock the wheels, is used by Chenard-Walcker and Bignan. There is a slight increase in the proportion of overhead valve engines, the overhead valve design being used particularly

in conjunction with detachable cylinder heads. Most of the overhead valves are operated by pushrods. The great majority of the entirely new models are fitted with Delco electric equipment, but none of the modified or remodelled cars take this equipment.

Three-speed transmissions are coming into more extensive use on the more powerful cars, while the majority of the cheaper and smaller models retain the four-speed gearbox. A great deal of development work seems to have been done on springs. Only three firms—Berliet, Lorraine-Dietrich and Bellanger—are adhering to the American type of car with large engine and of cheap production, whereas all of the other makers are turning out the European type of cheaper car with the smallest possible engine.

**FIGURES** made public by the Controller General of Civil Aviation in Great Britain show that from May, 1919, to March, 1921, 63,975 civilian airplane flights were made in the United Kingdom, averaging 19 minutes per flight. The planes flew a total of 1,593,700 miles in the 23 months.

More than 170 tons of freight and 110,388 passengers were carried.

Goods imported by airplanes during that period totalled in value 818,553 pounds sterling and exports aggregated 402,776 pounds.

In France civilian airlines imported 2,041,400 francs worth of goods during the first quarter of this year. Exports by air amounted to 660,200 francs.

---

**T**HE exceptional interest shown by the public in the Paris show has made French manufacturers hopeful that the worst of their depression is past. The high gasoline taxes, which continue to hinder sales, are reflected in the engineering trends at the show. The dominating type is a light 4-passenger, 4-cylinder car of 120 cu. in. piston displacement or less. The French automotive engineers have made definite efforts to attract buyers through designs which make for fuel economy.

---

# New German Car Has Novel Design Features

The clutch design of this 30 hp. Protos is entirely new. The method of locking the gears in position is unusual. Cylinder block is an excellent example of German engineering and foundry practice. There are no control hand levers on steering wheel. Four-cylinder engine used.

By Benno R. Dierfeld

**T**HE large Siemens electrical manufacturing company in Siemensstadt, near Berlin, about seventeen years ago established a branch factory for the manufacture of automobiles. Its line of cars have been sold under the trade name of Protos and have enjoyed a wide market. A number of the chief components of the latest 30-hp. Protos model are illustrated herewith. The car is fitted with a four-cylinder 80 x 130 mm. (3.15 x 5.12 in.) engine.

The four L-head cylinders of the engine are cast in a block, with the heads integral. The crankcase is divided horizontally. Cooling is by thermosyphon circulation, ample water spaces being provided. The aluminum fan is driven by a fabric belt. The crankshaft is carried in three babbitt bearings in the upper half of the crankcase. The pistons are of cast iron with three rings, and the piston pins are fixed in the piston bosses. The valves have adjustable tappets and are enclosed by large aluminum cover plates. The camshaft is driven by an enclosed, silent chain which also drives the high tension magneto. The latter is a special enclosed type built by the Siemens concern, and is located at the right hand side.

An electric generator is arranged on the right hand side and driven by a fabric belt from the front pulley; between the crankcase arms extend cast aluminum filler plates or continuous webs which form bases for the magneto and generator and replace the usual noisy sheet steel underpan. The Zenith carburetor is located on the left hand side, the mixture passing from it through a cored hole in the cylinder block. Lubrication is by a circulating system with gear pump. One of the illustrations shows different sections of the cylinder block. This is a very fine example of German engineering and foundry practice. The arrangement of the internal gas passages and the ample water space can be clearly seen from these drawings.

The flywheel is made from a forging, the objects being to obviate all danger of bursting and to eliminate or at least minimize the rejections which are said to be numerous with cast flywheels; its rim has the usual gearing for the electric starter.

The clutch is an entirely new design. The flywheel is formed with an annular Vee groove that forms the female double cone. The male double cone consists of a number of suitably cut leather disks, which are held to the aluminum clutch plate with a dovetail joint and are further secured by screws. This leather double cone with the clutch plate is pressed against the flywheel by means of the usual coiled clutch spring. When the clutch is en-

gaged there is no axial thrust on the main bearings of the crankshaft. Declutching is effected by means of a divided coupling sleeve on the hollow clutchshaft. In order to remove the leather disks, screw *a* in the clutch plate is loosened, after which the filling piece *b* in the dovetailed groove may be removed and the screws loosened. The coupling sleeve is lubricated by means of a snap lid oil cup. The transmission has four forward speeds and reverse and several sections of it are shown. There are three shifter bars with the usual forks engaging into slots on the gear hubs.

Quite interesting is the manner of locking the gears in position. For this purpose the shifting lever shaft is provided with a lever *A*, having two arms *A<sub>1</sub>* and *A<sub>2</sub>*. The lower end of arm *A<sub>1</sub>* engages between the two lugs on the upper side of the shifter bars and the lower end of arm *A<sub>2</sub>* carries the sickle-shaped piece *S*. Furthermore, there is arranged transversely to the shift bars a locking bar *B*, with two milled notches *D* and *E*. The shifter bars also have two lugs on their under side. The sickle-

Sectional view of friction clutch showing leather annulus with its engaging edge tapered inside and out

The Protos has never been sold in this country but became somewhat known here through its participation in the New York-Paris race in 1908. It arrived in Paris first but was disqualified because of having used the railroads in the western part of the United States, and a Thomas car was declared the winner.—EDITOR.

shaped piece *S* of the gear shift lever engages in the notch *D*, where a guide roller *R*, for the straight side of *S* and a spring loaded roller *R*, for the curved back side of *S* are provided.

As soon as the gear shift lever is moved axially, piece *B* is moved axially too, because the sickle *S* engages in notch *D*, and its milled notch *E* opens the way for the middle gearshift bar, while the other two shifter bars are locked by piece *B*, engaging their lugs on the under side. Now the shifter lever can be swung sideways and the desired gear engaged. Finally, the spring-loaded roller engages the corresponding notch on the back side of the sickle *S* and locks the gear in position.

When any forward gear is engaged the two reversing gears are at rest, thus consuming no power.

All transmission shafts run in ball bearings; the transmission case has a cover with which the gearshift gate is cast integral, thus facilitating the mounting of the transmission in the chassis. Lubrication of the transmission is entirely with oil, the supply is replenished through a snap cover filler *O* so arranged that the oil level in the transmission case is limited as to height, thus avoiding oil waste or power loss due to too high an oil level. The oil cup on the upper part of the transmission case serves to lubricate the universal joint.

The brake at the rear of the transmission is operated by pedal, shaft and toggle; its shoes are lined with cast iron. Adjustment can be effected at the pedal and by a small hand wheel on the brake itself.

The combined universal and slip joint runs in oil and its case encloses the pulley of the speedometer drive. The drive shaft runs in ball bearings in the torsion tube; the front bearings are lubricated by an oil tube from the

Front axle end, knuckle and inner hub

transmission case. The rear axle housing is of cast steel with pressed-in steel axle tubes; the bevel pinion shaft runs in one large and one small ball bearing, the thrust being taken near the universal joint.

The rear-axle is semi-floating. The steel wheels are fitted to a conical hub and can easily be removed with a special spanner. The rear brakes are expanding brakes and can be adjusted by means of a fluted disk.

There are no control hand levers on the steering wheel, for the magneto has automatic spark advance and the throttle lever is replaced by a rotatable sleeve below the steering wheel. This arrangement is preferred by the Protos designers, because the throttle lever interferes somewhat with the steering and is rarely used if an accelerator pedal is provided. The very simple connection of the accelerator pedal with the throttle lever tube, by a cam, is clearly visible from the drawing. Steering is by a steel worm and sector with large surfaces, and adjusting

Pedal assembly and sectional views of rear axle and forward end of propeller shaft

Above: Sectional views and details of cylinder block. Below: Views of the gearbox, control and service brake

means are considered superfluous. The sector forms one piece with the steering arm, thus increasing the security.

The front axle is of the Mercedes type. The ball heads of the steering knuckle arms are below the tie rod, so the latter could not drop to the road if it should become detached. The ends of the tie rod tube are rolled into the annular grooves of the fittings. This is claimed to result

in a very dependable joint, avoiding the danger of burning the metal in brazing. Within the wheel hub there is a small ball bearing at the outer end and a large double row ball bearing at the inner end. The steering knuckle pivot has plain bronze bushings, with a large steel ball taking the axial thrust. Front and rear steel wheels can be exchanged.

## A New Gear Box of Swedish Origin

**A** MOTOR car change gear has been invented by L. A. Pettersson, a Swedish engineer, a representative of whom is now in this country. The chief feature of the new gear is that for all forward speeds the power passes through the gearbox in a straight line, from the first motion shaft to the tailshaft arranged co-axially therewith, so that the usual secondary or countershaft is eliminated. The transmission shown herewith is designed to afford four forward speeds and one reverse, including a direct drive. The gearing itself is exceedingly compact, and that the complete gearbox is of about the same size as the conventional box is due to the fact that it also encloses an intermediate shaft with two universal joints, which permits of giving the single driving pinion, when changing from one speed to another, a radial as well as an axial motion. The gear is known as the Centrali.

As will be seen from the illustrations, the primary shaft consists of three parts. The first part is mounted in the outboard bearing at the clutch end and connects to the clutch shaft or sleeve. The second or intermediate part connects the two universal joints and incorporates a sliding joint. The third part, which carries the single driv-

ing pinion, is mounted in a bracket swiveled around a pivot in the lower part of the case. By moving the bracket axis different distances from the outboard bearing axis the pinion and its shaft can be slid into mesh with one or the other of four concentric internal gears all secured to the driven shaft. Operation of the gear is effected by a single lever at the side of the case which has both a sliding and a rocking motion. The sliding bearing supporting the driven pinion is first rocked into the position corresponding to any particular gear and is then shifted into mesh lengthwise. When in mesh the bearing bracket is held against lateral strains by a locking key which enters a slot in a sector plate, and it is held against longitudinal strains by the usual spring-pressed plunger. The reversing pinion rotates only while actually in use, and when not in use disappears in a recess.

A number of advantages are claimed for this change gear, the principal one being silent operation. All bearings are of the anti-friction type. As compared with the conventional type the gears are fewer in number but larger in size, since the total reduction is made in one step instead of two.

Primary shaft showing three parts

# Unconventional Sporting Airplane a New French Product

Unusual four-cylinder engine in airplane of original design. Duralumin combined with ordinary wood and fabric in construction of frame. Manufacturer also produces larger planes for passenger carrying.

By John Jay Ide

THE aviation firm of Henry Potez came into existence during the war, when it constructed a considerable number of airplanes to the designs of other makers. After the war Henry Potez undertook the production of airplanes of his own design, the most unconventional of which is known as Type VIII. This machine is of the so-called sporting type and is fitted with a most unusual 4-cylinder engine, also designed by Henry Potez and described below.

In the Type VIII Henry Potez biplane duralumin is employed for the channel section wing spars, wing ribs and the framework of the fixed and movable portions of the tail. The longerons and struts of the fuselage are also of duralumin, while the fuselage covering is of plywood. It remains to be seen whether this compromise between all-metal and the ordinary wood and fabric construction has pronounced advantages.

The landing carriage has four wheels and, due to the low position of the fuselage, the struts connecting the axles with the fuselage are commendably short. A sprag brake, pivoted to the center of the rear axle and operated from the pilot's seat, reduces rolling after a landing has been accomplished. The machine can be landed at only 25 miles per hour, owing to the low wing loading—4.5 lb. per square foot.

The pilot is placed in the rear seat, and, as the passenger is placed at the center of gravity, the machine can be flown in his absence without compensating ballast. Double control is provided.

The specifications of the Type VIII Henry Potez are:

Span (upper plane) .....	26.2 ft.
Span (lower plane) .....	22.3 ft.
Total length .....	18.4 ft.
Length of fuselage .....	15.4 ft.
Total height .....	8.0 ft.
Wing area .....	205 sq. ft.
Wing chord .....	4.6 ft.
Wing gap .....	4.8 ft.
Aileron area .....	19.9 sq. ft.

Stabilizer area .....	15.6 sq. ft.
Stabilizer span .....	7.9 ft.
Elevator area .....	10.2 sq. ft.
Rudder area .....	4.8 sq. ft.
Fin area .....	7.0 sq. ft.
Weight empty .....	485 lb.
Live load .....	353 lb.
Fuel and oil for three hours .....	88 lb.
Total weight .....	926 lb.
Weight per sq. ft. ....	4.5 lb.
Weight per hp. ....	18.5 lb.
Factor of safety .....	7
Speed at ground level .....	75 m.p.h.
Climb to 6560 ft. ....	18 minutes

Type VIII Henry Potez biplane

## Novel Engine Has Vertical Crankshaft

The Type VIII model is equipped with a Henry Potez Type A-4, 50-hp. engine. There are four air-cooled cylinders in line with a vertical crankshaft. The heads face forward in order to insure adequate cooling. The propeller is driven through a bevel gear at the top of the crankshaft. This bevel gear also acts as a 2-to-1 reduction gear. Pressure lubrication is employed.

The special feature of this engine is that light weight has been sacrificed in order to obtain the strength of an automobile type of engine. The weight complete is 4.4 lb. per horsepower, a figure about double that of a number of aviation engines.

### Specifications:

No. of cylinders .....	4
Bore .....	3.93 in.
Stroke .....	4.72 in.
R.p.m. of crankshaft ...	2200
R.p.m. of propeller ....	1100
Hp. ....	50
Weight complete .....	220 lb.
Weight/hp. ....	4.4 lb.
Fuel consumption .....	4 gal. per hr.

For transport purposes Henry Potez supplies the Type S. E. A. VII. This machine is derived from the S. E. A.

The Henry Potez type S. E. A. VII passenger carrying biplane

IV C-2 military model, supplied in considerable numbers to the French army. The wing area, however, has been somewhat increased in order to improve the landing qualities. The design and construction are conventional. The pilot is placed aft of the 400-hp., 12-cylinder Lorraine-Dietrich engine and behind him is the nicely stream-lined cabin for two passengers.

This type of machine is being employed with success on the Paris-Prague and Paris-Warsaw commercial airplane lines.

The Type S. E. A. VII has the following specifications:

Wing area .....	474 sq. ft.
Span .....	45.9 ft.
Height .....	10.5 ft.
Length .....	30.2 ft.
Weight empty .....	2425 lb.
Personnel and luggage .....	661 lb.
Fuel and oil .....	551 lb.
Total weight .....	3637 lb.
Speed at ground level. ....	120 m.p.h.

## A Five-Speed Truck Transmission with Single Lever Control

**S**INCE pneumatic tires have come to be used extensively on trucks of moderate and larger capacities there has been need for transmissions with more than four speed changes. A number of such transmissions have been brought out. Most of these comprise a four-speed transmission with an extra two-speed gear connected in series therewith, so that any of the four forward speeds of the first gear can be combined with either the direct drive or the low speed of the second gear. While what is here described as two separate gears is generally enclosed in a single housing and forms a unit, two levers are required for operating the combination, which is something of an objection, even though one of the levers may not have to be operated very frequently.

A design of gear box for motor trucks giving five forward speeds and one reverse has been invented by A. G. Herreshoff and is illustrated by the accompanying drawings. It embodies many of the characteristics of the ordinary four-speed gear, and the third, fourth and fifth speeds are obtained in exactly the same way as the second, third and fourth speeds in a four-speed gear. One difference is that the constant mesh gears at the left hand end in the drawing are placed between two sets of ball bearings, the object being to limit the span between supports of the splined and secondary shafts.

Another difference is that the first and second speeds, instead of being obtained by double reductions, as usual, are obtained by triple reductions. It will be noticed that the pinions A and B on the secondary shaft are not fast upon that shaft like the rest of the pinions, but are free to revolve thereon on a roller bearing. These pinions are driven from the reverse gear shaft at a speed lower than that of the secondary shaft. The drive is from the reversing pinion C to the reversing gear D, from gear E to gear B and from gear B to gear F for the first speed or from gear A to gear G for the second speed.

The slider bars are arranged exactly as in a four-speed gear, there being three of these bars, each controlling a single gear on the splined shaft. In ordinary operation the truck would be started off on second gear and the first gear would be used only in emergencies. As the quadrant positions for the first gear forward and the reverse are opposite each other and this slot of the quadrant can be locked by means of a projection, operation of the gear is very simple. Moreover, manœuvering, which should be done on the first forward gear and the reverse, can be effected easily by simply moving the gear lever back and forth in the same

slot. Mr. Herreshoff maintains that the low gear reduction in the gear box should be about 9 to 1 in order that, on the one hand, the truck may be capable of running 15 m.p.h. at 1000 r.p.m. of the engine, and, on the other, there may be sufficient torque on low gear to slip the wheels. Such a high ratio of reduction is impractical with a double reduction in the gear box. Moreover, with only four steps in the gear box the individual steps would be so great as to make gear changing very difficult.

## Some Observations Regarding Aircraft Engines

**I**N an article on the New Aircraft Engines Commander Martinot-Lagarde of the French Army makes the following observations regarding various features of engine design:

In the case of cylinders with aluminum water jacket, a defect in the fit of the steel sleeve in the cylinder block entails the early scrapping of the whole assembly.

In engines on which the valves are completely enclosed the danger of coloring the valves by overheating is greater than in other engine types.

Valves with hollow, threaded stems are delicate. Where valves are operated by rocking levers the lubrication of the rollers presents a difficult problem.

Welding of the steel water jackets should be carried out with the greatest care, using very low carbon steel which does not air-harden.

Double valve springs are more dependable than single springs.

Water-tightness of the circulating pumps is more easily secured by means of gaskets than by means of conical joints.

Herreshoff gear box

# Directional Control of Tractors

Weak points explained in steering by retarding one side or the other of the tractor. Double engine offers possibility for betterment as does the brake and clutch method for heavy loads. A variable speed transmission with infinite number of speeds would solve the problem.

By Victor L. Darnell

**D**IRECTIONAL control for tractors of the track-laying type or the four-wheel drive type, where steering is accomplished by retarding one side or the other, offers many perplexing problems. There are two distinct conditions under which the tractor must be steered or directed; under a heavy load and under a light load. Directional control is easier under heavy loads than under light loads, as far as making even turns is concerned. Under light loads the tractor tends to produce a jerky or zig-zag action. However, it is under a light load that sensitive directional control is most needed in farming operations, such as cultivating, mowing, etc. It is the purpose of this article to show how sensitive steering might be accomplished.

Several of the different methods that have been used are described below and their weak points are explained.

## The Differential Method

The differential used with this method (Fig. 1) is exactly the same as that used in the automobile, but two brakes, C and D, are added. If the ground resistance is the same under both driving wheels, E and F, the tractor will continue in a straight line, but this is rarely the case and it is necessary for the operator to constantly tighten and loosen the brakes. Then, the use of brakes spells a waste of energy and as long as there is a slipping action under the brakes there is a loss of power; however, when the brake is locked and only one side turns, there is no loss except that in the differential gearing. The brake is applied on the side to which the tractor is to turn, and this involves one of the biggest draw-backs to this type of directional control. As one side slows up the speed of the other increases correspondingly until one side is locked and the other is go-

ing twice the original speed, which means that to keep the tractor going at a constant speed the engine must be slowed down to one-half its original speed and, roughly speaking, only one-half of the engine torque is carried to that wheel. This is one of the reasons that tractors of this type do not travel in a straight line, but follow a zig-zag course, especially under light loads.

Another bad feature is that the outside wheel should receive the maximum power in turning but is robbed of one-half that is coming to it. Then if one side gets in a mud hole the total turning effort is limited until a brake is applied on that side, and when this is done directional control is lost and the tractor must go whichever way it can until dry ground is reached, which may put the tractor in a still worse place. This could be partially remedied by locking the differential and driving straight ahead, but, of course, directional control would be sacrificed for the time being.

It would naturally come to one's mind that if the one side speeds up with a retarding of the other, why not put in a mechanism that would gradually neutralize this speeding up or, in other words, keep the engine speed constant or nearly so. In this manner conditions in turning would be bettered, but the other defects mentioned in the plain differential method would still be existent.

## Fixed Ratio and Clutch Method

There is a clutch and change gear speed ratio for each side of the tractor, as shown, for this type of directional control.

By releasing a clutch the gear change could be accomplished. This could also be accomplished by replacing the gear change with another clutch of different speed

Fig. 1—The differential method

Fig. 2—Constant speed differential method

Fig. 3—Fixed ratio and clutch method

Fig. 5 (Right)—Indicating progressive action of brake and clutch

than the first one. If these clutches are capable of a slight degree of slippage then a curve would be turned with any desired radius and the power would be on the outside wheel in making the turns. If the steering is accomplished by the slipping clutch then the more evenly the clutch would slip under a heavy load, and hence the even the turn. The more speed changes or the more clutches we had the more definite radii we could turn. The application of a brake would help directional control under light loads, and it might be necessary to lock the side in neutral with the brake when making a sharp turn.

#### The Brake and Clutch Method

If the clutch is sensitive enough, turning a large radius under heavy loads could be accomplished by means of the clutch alone and the use of the brake could be reserved for sharp turns, by releasing the clutch and applying the brake. For light load steering the clutch and brake action would have to overlap to prevent a zig-zag action of the tractor.

This can be explained by assuming the total movement of the clutch from open to closed to be divided into 10 parts and the movement of the brake the same. If the clutch was 10 points closed the brake would be one point on, and so on, until the clutch was entirely on and the brake entirely off, or vice versa. The checked area would represent a frictional loss and would occur only as the clutch was acting, there being no loss when the clutch was wholly engaged or disengaged. It would seem that at point 5, where the brake movement equals the clutch movement, there would be no movement of the tractor

Fig. 4—Brake and clutch method

on that side, yet it would have a tendency to move forward. This can be explained by assuming one side of the tractor only connected to the motor. The tractor will then move in a straight line, provided there is no load on it due to its construction. There are then two alternatives, one being to apply a brake to the free running side and the other to add a load to the tractor to produce its easy turning.

There are several other methods of directional control which have possibilities.

#### The Friction Drive

This friction drive could be made cheaply and sensitive enough for light work.

If a variable speed transmission could be devised with an infinite number of speeds and at the same time cheap to manufacture, durable and efficient, the problem would be practically solved. The magnetic transmission would accomplish the desired results, but would be too intricate and expensive. The hydraulic transmission would also answer the purpose, but its low efficiency, cost and number of parts required make it prohibitive.

The variable crank and ratchet looks very promising, but has never come to the front.

By simply moving the cam eccentric A around, the throw of the arm B is varied. By using three eccentrics the shaft C is given a fairly constant speed.

The steam tractor with an engine on each side would produce the best results that could be wished for. By simply operating a two-way valve the speed of either side could be controlled within the narrowest limits, and differentiation of power would be complete.

Fig. 7 (Above)—The variable crank and ratchet method  
Fig. 6 (Left)—The friction drive method

# Permanent Top Viewed with Favor in Many Quarters

Few manufacturers will displace collapsible top on their 1922 models but many believe the trend is in the direction of the permanent type. Heavy buying of enclosed cars indicates that the public no longer insists that the top be lowered. Considerable interest aroused by questionnaire.

**T**HE permanent top as standard equipment for passenger cars will not become general on 1922 models, but a growing tendency on the part of the buying public to favor a change from the collapsible top has caused a majority of manufacturers to give serious thought to the question. Certain models of a few makes of cars will appear with the permanent top this season and several manufacturers will be prepared to furnish such a top on special orders.

The type of permanent top that has been seen the most is what is known as the California top. This has been extremely popular in far western states. Everyday observation proves that in most other sections of the country the average car owner seldom lowers his collapsible top. The enormous increase in the sale of sedans and coupés indicates that many buyers no longer care whether a top can be lowered or not. It was these tendencies on the part of the public that caused AUTOMOTIVE INDUSTRIES to conduct a survey, which has recently been completed, asking manufacturers whether or not they planned to use the permanent top as a part of their equipment on the 1922 models and whether or not they felt that the tendency of other manufacturers was toward such a move.

Replies to a questionnaire from 49 manufacturers, who produce more than 75 per cent of all cars manufactured in the United States, showed that of this number there are 11 who expect to use the permanent top as a part of their standard equipment on one or more models. Five more said they would be prepared to furnish the top on special orders. The California top will be used on 6 of the 11 makes of cars that will have it as a part of their equipment, while the others will use those of their own design. But one of the 5 who will supply the tops on special orders will use their own model, the others planning to use the California top.

The survey showed that a genuine interest was being taken by manufacturers in the issue and 33 of the 49 said they felt that the tendency among other manufacturers was toward planning for such equipment. Only five said they thought there was no general movement along this line and 11 were non-committal.

The principal objection to a permanent top is the increased cost of manufacturing. Several companies reported that they felt that there is an increasing tendency on the part of the public to desire the change, but increased production costs would demand increased selling costs and in lieu of the period of industrial depression that has been upon the country, economy is the most desirable factor to maintain so long as it can be done without impairing efficiency and quality. The question of shipping also comes into the discussion, for many cars are being shipped from the factories in double decked loads. With a permanent top this, of course, would be

impossible unless some means could be devised whereby the top could be shipped in parts and assembled when it reaches the dealer.

Arguments in favor of this type of top, however, appeared. Some of the principal reasons why manufacturers feel that the tendency is favorable are:

1. Public satisfaction.
2. Cheaper cost as compared to the sedan or coupe.
3. Appearance.

In order to discover whether or not the public particularly desires a top that can be let down it is only logical to determine whether or not there has been a heavier demand for closed cars in the past few years than before. Figures for 1919 show that 161,000 closed cars were sold to the public. In 1920 a total of 320,000 were sold. The closed cars in 1919 amounted to 10 per cent of the entire number produced and in 1920 to 17 per cent. Figures for 1921, of course, are not available, but indications point to the fact that even a larger number will be sold. It is almost certain that the total production in 1921 will not reach the figure attained in 1920 when 1,883,000 cars were produced. This is due to industrial depression, but at the same time the demand for coupe and sedans is already ahead of production on several models.

Although expense of production was given as one of the reasons some manufacturers do not look with favor upon the permanent top, others pointed out that it is cheaper than the enclosed car. It has been shown that there is an increased demand for enclosed cars, and it is logical to assume that if the public is willing to buy coupe and sedan models of cheaper cars then a model combining the advantages of both the open and closed car would not prove a drug on the market. Figures have been compiled showing that the public does buy the cheaper models of enclosed cars. Ten companies, manufacturing these models at prices ranging from \$695 to \$2,885, had much larger sales than did companies manufacturing sedans and coupes of a more expensive nature. And a study of price lists will prove that there is a difference of from \$245 to \$500 between the prices of open and enclosed models of these ten makes of cars.

As far as appearance is concerned, that is largely a matter of personal opinion. There can be no doubt that many graceful lines have been brought out in the standard collapsible top. The general trend of opinion, however, indicates that the manufacturer as well as the public is convinced that there is more beauty and style in the permanent top.

A broad view of the situation does not indicate any immediate revolutionary movement toward standardizing this type of top, but there does appear a growing tendency to look with favor upon such action.

# The Testing of Motor Fuels

## Part I

A brief manual outlining the need for the testing of motor fuels, and showing how the results of tests are interpreted, especially in relation to their effect upon the engine and its performance.

**T**HERE is a wide variation in the quality of commercial gasolines and a wide and increasing distribution of blended fuels, particularly those containing benzol. This makes it essential that all gasoline used in engineering development or motor testing work be examined for its composition and properties. Accurate information on the quality and composition of gasoline used in such work is essential to the making of a proper decision as to whether the results obtained should be attributed to the engineering design or to the quality of the fuel used. Some of the factors which have a marked influence on the behavior of gasoline are:

- 1—Initial boiling point, because of its effect on starting.
- 2—Height of distillation curve and position of 85 per cent point, because of influence on such factors as distribution, knocking, carbonization and contamination of lubricating oil.
- 3—Content of alcohol and of aromatic hydrocarbons (benzol and similar materials), because of the smoothness and relative freedom from knock which characterizes the combustion of such materials.
- 4—Percentage of unsaturation, because of the gums which are formed from the unsaturated constituents, and which are then deposited in the induction system and on intake valves.

Fortunately, the commercial examination of gasoline is a comparatively simple matter and can be made by any technically trained man with a minimum of equipment.

If the gasoline is composed entirely of Eastern or Mid-continent petroleum oils, the determination of the following factors gives sufficient information on the characteristics of the material in practically any case to indicate whether it is suitable for use.

- 1—Specific gravity.
- 2—Distillation range.
- 3—Acidity.
- 4—Percentage of unsaturation.
- 5—Content of gummy materials.

In addition to methods for determining the above factors and for interpreting the results obtained, methods will also be given for obtaining the following data on a motor fuel:

- 6—Percentage content of aromatic hydrocarbons (benzol).
- 7—Purity of a fuel as to its content of paraffin hydrocarbons.

- 8—Content of alcohol.

### INTERPRETATION OF RESULTS

#### 1—Specific Gravity

The specific gravity of a gasoline is of importance only in that, when taken together with the distillation data, it serves to indicate the presence of any considerable percentage of materials other than those normally present in gasoline, such, for example, as benzol.

The normal specific gravity of commercial gasoline from Eastern or Mid-continent crude oils is around 0.740 to 0.745. Gasoline from California crude oil having approximately the same boiling range, has a specific gravity around 0.760.

The specific gravity of motor benzol is 0.877 to 0.879. The gravity of a gasoline-benzol blend is approximately the average of the specific gravities of the two ingredients, taken in the proportions in which they are present. (Because of a slight increase in volume which occurs when gasoline and benzol are mixed, the gravity of a blend is only

a close approximation to an average of the gravities of the two ingredients.) Hence, if the specific gravity of a gasoline from the eastern half of the United States is above 0.750, its distillation data should be examined for an indication of the presence of benzol.

#### 2—Distillation Range

The most important items of information on the properties and characteristics of a gasoline which may be obtained from its distillation data are,

- a—Starting qualities.
- b—Ease of vaporization and distribution.
- c—Tendency to contaminate the lubricating oil.
- d—Composition (to some extent), particularly presence of benzol.
- e—Knocking characteristics (if the source and composition of the fuel be known).
- f—Tendency to deposit carbon in engine cylinders.

The distillation data of a gasoline can usually best be interpreted by plotting temperature against per cent distilled, as illustrated in Figs. 1 to 3. The distillation data arranged in this way is interpreted as follows:

- a—Starting Qualities. A low initial, 5 per cent distilling below 55 deg. C. (131 deg. Fahr.), characterizes a fuel of good starting qualities. Similarly, a high initial indicates poor starting qualities. Thus, in Fig. 2 the fuel having distillation char-

**T**HIS manual, prepared in the form of a bulletin by the Fuel Section of the General Motors Research Corporation and edited by T. A. Boyd, contains much useful information which, so far as we are aware, has not heretofore been published in the concise and usable form in which it is here produced. Part II, which will appear in an early issue of *Automotive Industries*, gives in detail the methods followed in making tests of motor fuel and a description of the simple apparatus used in these tests.

Fig. 1—Distillation curves of various grades of gasoline. Fig. 2—Distillation curves: A, for a gasoline corresponding to Government specifications, and B, for a commercial gasoline of lower average boiling point. Fig. 3—Distillation curves of commercial gasoline, and of gasoline-benzol blends. Note flattening of the curve in the 10 to 70 per cent range in the case of the blended fuels. Fig. 4—Curve showing the lowest temperature at which a gasoline with the distillation curve shown can be completely vaporized under ideal conditions

acteristics as shown in Curve B, has superior starting qualities to the fuel distilling as in Curve A.

- b—Ease of Vaporization and Distribution. The lower the distillation curve, the more easily a fuel may be vaporized. The distillation curves of nearly all commercial gasolines of the present lie within the range given in Fig. 1. The average volatility of commercial gasoline varies considerably from time to time. For this reason it is impossible to give a narrow range of values which will include the distillation curves of the gasolines that are sold for motor fuel commercially. For a like reason it is important that the distillation data of a gasoline, which is used in any experimental or testing work be known.

Especially is this true if comparative tests are being made in which more than one gasoline is used.

The results of recent work show that the temperature at which 85 per cent of a gasoline has distilled is of most importance in indicating its vaporization and distribution characteristics.\* An empirical rule for determining the lowest mixture temperature at which complete vaporization or a dry mixture is possible for a 12:1 mixture is as follows: (This rule applies only to paraffin base gasolines.)

Temperature of 85 per cent point in degrees Centigrade — 135 = minimum dry mixture temperature, in degrees centigrade.

Temperature of 85 per cent point in degrees Fahrenheit — 243 = minimum dry mixture temperature, in degrees Fahrenheit.

These are the saturation temperatures, or dew points of 12:1 mixtures of air and gasoline. It

\*Work done at the Research Laboratory of Massachusetts Institute of Technology under direction of R. E. Wilson. See *Journal Society of Automotive Engineers*, October, 1921, pp. 265-8, published complete in *Journal of Industrial and Engineering Chemistry*, Vol. 13, No. 10, October, 1921, pp. 906-12.

Figs. 5 and 6 show curves plotted from data (taken from Fig. 3) relating to the distillation curves of gasoline-benzol blends

is not possible commercially to obtain complete vaporization at these temperatures, but they may be used as an ideal upon which to base the performance of hotspots, etc. Fig. 4 illustrates the use of this rule in a graphical way.

c—Tendency to Contaminate the Lubricating Oil. Insofar as the nature of the fuel is a factor, the higher the 85 per cent point, the greater is the tendency toward dilution of the crankcase oil.

d—Composition, Particularly Presence of Benzol. A flattening of the distillation curve in the 10 to 70 per cent range (see lower curve in Fig. 3) usually indicates a blend. The gravity of the fuel should be noted in this connection. If it is high (above 0.750 for a fuel having an 85 per cent point not over 185 deg. C.), it indicates the probable presence of benzol. These same indications apply also to blends containing alcohol. Alcohol boils at about 78 deg. C. (173 deg. Fahr.) and has a specific gravity around 0.820. Alcohol alone is not soluble in gasoline unless practically no water is present; so that an alcohol-gasoline blend must contain a third material which serves as a binder, for which purpose benzol has mostly been used. If the distillation curve shows any peculiarity which might indicate a blend, it is of advantage to arrange the distillation data as shown in Figs. 5 and 6, plotting values taken from the ordinary type of curve referred to above.

The curves are plotted as in the following example: Assume that the initial of the gasoline is 50 deg. C. as in Fig. 3. A point is then located on the O vertical line at 50 deg. (Fig. 5). From the distillation curve (Fig. 3) the number of cubic centimeters coming over from 50 deg. to 60 deg. is noted, and this value is plotted as a point on the vertical axis at 55 deg. as in Fig. 5. In like manner the number of cc. distilling from 60 deg. to 70 deg. is plotted on the vertical axis at 65 deg. The same procedure is followed successively for the ranges 70 to 80, 80 to 90, etc. The area under the curve so obtained is proportional to the volume distilled, and any constituent which is present in considerable amounts produces a peak on the curve at about its boiling range.

Motor benzol boils at 80 to 170 deg. C. (176

to 338 deg. Fahr.) and considerably more than one-half of it comes over below 100 deg. C. (212 deg. Fahr.); so that its presence in a gasoline in any considerable percentage can readily be observed from the peak on the curve which shows the large amount of material coming over in its distillation range.

Because of the smoothness and freedom from knock with which the combustion of aromatic hydrocarbons (benzol and similar materials) is characterized, even at very high compressions, the presence of any considerable percentage of such materials in gasoline imparts combustion characteristics to the gasoline which do not belong to it alone and which it does not have commercially.

e—Knocking Characteristics. For fuels which are composed of paraffin hydrocarbons, the tendency to knock increases with distillation temperature. However, the knocking characteristics of a fuel are determined primarily by the nature of the materials of which it is composed, and secondarily by its distillation temperature. For example, a fuel which contains such materials as benzol or alcohol shows a decreased tendency to knock in proportion to the percentage of such material present. Most commercial gasolines as sold east of the Rocky Mountains are composed mainly of paraffin hydrocarbons, but the knocking characteristics of a fuel can be obtained from its distillation curve only when the composition of the fuel is known.

f—Tendency to Deposit Carbon in Engine. The amount of carbon which is formed in an engine from the fuel used increases with the distillation temperature of the fuel.

The height of the 85 per cent point gives a measure of this factor.

Because the amount of carbon deposited in an engine varies with a number of factors, no quantitative values can be given in this connection. Insofar as the fuel is a factor, however, the higher its distillation temperature the greater the amount of carbon deposited under any given set of conditions.

### 3—Acidity

Test should show no acidity. Acidity in gasoline indicates either (a) that the sulphuric acid used in refining was not completely removed from the gasoline, or (b) that either sulfonic acids or neutral esters of sulphuric acid were formed in the gasoline in the effort to produce a white product, and were not subsequently removed. The presence of any of these acid materials is harmful and unnecessary.

### 4—Percentage of Unsaturation

For development and testing work the unsaturation of a gasoline should not exceed 6 per cent, as determined by absorption in cold concentrated sulphuric acid.

The unsaturated or olefine hydrocarbons in gasoline are produced by cracking. They are characterized by the tendency of the molecules to polymerize or hook together with the consequent formation of larger molecules, some of which are gums or tars. While this action

goes on to some extent in gasolines containing only a small percentage of unsaturated materials and at ordinary temperatures, it increases with the percentage of unsaturation and it is very greatly accelerated by increase in temperature or the presence of acid materials. Trouble arising from the unsaturated constituents in gasoline is not common. If the percentage of unsaturation is high or the gasoline is old, tars are deposited in the induction system and especially on intake valves.

The percentage of unsaturation should be interpreted in connection with the content of gummy materials, as described immediately below. A gasoline which is low in unsaturation but which deposits a considerable amount of gums on evaporation is fully as unsatisfactory for use in testing work as is one which is high in percentage of unsaturation, but which gives little or no gums upon evaporation in the standard test.

#### 5—Content of Gummy Materials

If a weighable amount of gum (or an amount which is distinctly visible in the dish) is deposited, the gasoline contains either gums as such, or undesirable gum-forming constituents.

Acid residues will show as gum in this test.

If the gasoline contains any dissolved elemental sulphur, the bottom of the dish will be colored gray or black.

This test should be interpreted in connection with that for percentage of unsaturation, as described immediately above.

#### 6—Percentage Content of Aromatic Hydrocarbons (Benzol)

Benzol will stand compression pressures in excess of 200 lb. per sq. in. without knocking, and it imparts this characteristic to a gasoline or naphtha with which it is blended in proportion to the percentage of benzol present.

Fuels which contain benzol are therefore not comparable to commercial gasoline in the operation which they give in an engine.

Blends of benzol and petroleum oils containing from 20 to 60 per cent of benzol have been sold, and benzol has been blended with petroleum oils ranging from gasoline through the naphthas to kerosene. If desired the distillation range of the petroleum oil after it has been freed from benzol may be determined, but the character of the petroleum oil can be judged largely from its gravity after nitration and by the distillation curve of the original blend.

#### 7—Purity of a Fuel As To Its Content of Paraffin Hydrocarbons

The gasolines sold east of the Rocky Mountains are composed mainly of hydrocarbons of the paraffin or chain type of structure. To these materials is due the characteristic operation of the commercial gasolines produced from our eastern and mid-continent crude oils, particularly the knock which begins to be apparent at about 75 lb. per sq. in. compression pressure. Some gasolines, especially those produced from California crude oils, contain considerable percentages of naphthene hydrocarbons. The naphthenes have the saturated ring structure, and, when compared for a given distillation range are characterized by higher specific gravities and by the ability to withstand much higher compressions without knocking than the paraffin hydrocarbons. For this reason the gasoline which is used in any testing work in which knocking characteristics are an important factor, should be tested for its purity as to content of paraffin hydrocarbons. This is best done by determining the temperature of dissolution (T. D.) of a

50-50 solution aniline and the fuel, or more accurately, the temperature of critical dissolution (T.C.D.) of the fuel with aniline, as described later.

If the T. D. or the T. C. D. is found to be approximately 70, the fuel is composed entirely of paraffin hydrocarbons. If, after the fuel has been nitrated and washed until it is entirely free from aromatic and unsaturated olefine hydrocarbons, it gives a low T. C. D., 30 to 55, the material thus obtained is not a pure paraffin fuel; but contains a considerable percentage of naphthene hydrocarbons, and is, therefore, not representative of the majority of the commercial gasolines in use in the United States.

#### 8—Content of Alcohol

Alcohol, like benzol, can be used at compression pressures considerably above 200 lb. per sq. in. without knocking. It imparts this characteristic to a gasoline with which it is blended in proportion to the percentage of alcohol present, a smaller percentage of alcohol than benzol being required for a given suppression of the knock.

Fuels which contain alcohol are, therefore, not comparative to commercial gasoline in their operation in an engine.

Some alcohol-benzol-gasoline blends have been sold as motor fuel, but the amount of such material is small and its distribution is not wide. Commercial alcohol alone is not miscible with gasoline. An alcohol-gasoline or alcohol-naphtha blend must contain a third material which acts as a binder, for which purpose benzol has been most frequently used.

#### Heat Content of Motor Fuels

Alcohol has a much lower heating value than gasoline or benzol, about 80,000 B.t.u. per gallon for alcohol as compared to about 120,000 for gasoline and 130,000 for benzol.

(To be continued)

### A "Trade" Motor Car

**S**PECIALLY designed motor cars carrying samples of textile and drapery goods will soon begin a tour of the European continent under direction of members of the British drapery and clothing associations.

This scheme is in line with the trade ship idea that is to be promulgated—ships carrying the goods of various manufacturers to different ports of the world where buyers may inspect them. Spain will be the first country visited by the motor car exhibits, and naturally the plan has advantages over the maritime exhibits in that inland cities and towns can be visited.

### A New Model Shock Absorber

**A** NEW model shock absorber, shown in the accompanying cut, is being manufactured by Edward V. Hartford, Inc. The new model operates on the same principle used in the former Hartford absorber, but a tubular link now connects the arm of the shock absorber with the axle. Ball sockets at each end allow free side play.

shock absorber

# Illinois Highway Department Makes Road Tests

New devices used in research work to determine comparative strength of various types of road pavement. Uniformity of subgrade under each of sections of road discovered by observations for moisture content and bearing power of soil under static and impact loads.

By Clifford Older and H. F. Clemmer\*

**C**ONCURRENTLY with the experiments carried on by the Federal Bureau of Public Roads at Arlington, Va., the Division of Highways, Illinois Department of Public Roads, is conducting research work in road building near Springfield, on what is known as the Bates Road, which parallels the Wabash Railroad for a distance of  $2\frac{1}{2}$  miles. This road is on a relocation, and the fact that the old road will accommodate traffic for any reasonable length of time makes it possible to close the test road to all but carefully controlled test traffic. There are no curves in the road, and the grades do not exceed 0.4 per cent. The subgrade soil is a brown silt loam, except for two small stretches where it more nearly approaches gumbo. The road is surfaced with seven general types of pavement, as follows:

1. Portland cement concrete.
2. Three- and 4-in. lug brick constructed monolithic with a Portland cement concrete base.

\*Chief engineer and engineer of tests of the Illinois Highway Department.

Fig. 1 (Left)—Goldbeck apparatus for determining subsoil impact bearing power. Fig. 2 (Right)—Apparatus for determining bearing power of subsoils under static loads

3. Three- and 4-in. lug brick constructed semi-monolithic with a Portland cement concrete base.

4. Three- and 4-in. bituminous-filled lug and lugless brick on Portland cement concrete base.

5. Three- and 4-in. bituminous-filled lug and lugless brick on macadam base.

6. Asphaltic concrete with and without binder course on Portland cement concrete base.

7. Asphaltic concrete with and without binder course on macadam base.

The series of test sections for each type or design cover all reasonable variations in strength that might be expected to give any degree of satisfaction under heavy traffic. Each series begins with a section roughly estimated to be equivalent in strength to 4 in. of concrete and increases to the approximate equivalent of 9 in. of concrete. In comparing the strength of concrete pavements with other types the following assumptions were made:

1. That a brick pavement constructed monolithic or semi-monolithic with concrete base has a strength equal to that of a concrete pavement of the same thickness and of the same quality of concrete as that used in the monolithic brick base.

2. That bituminous-filled brick on a concrete base has a strength equal to that of a concrete slab having a thickness equal to that of the base plus one-half of the thickness of the brick surface.

3. That bituminous concrete surfaces of 2-in. wearing course or  $1\frac{1}{2}$ -in. wearing course with  $1\frac{1}{2}$ -in. binder course have strength equal to 1 in. of concrete.

## Moisture Content and Bearing Power

For the purpose of determining the uniformity of the subgrade under each of the 63 sections comprising the road, observations were made for moisture content and bearing power of soil under both static and impact loads at points 25 ft. apart along the center of the roadway. These observations were made immediately before pouring of the concrete. In addition, samples of the subgrade, secured from different points along the road, were sent to the United States Bureau of Public Roads for soil analysis and laboratory determinations of bearing power.

All materials used in the construction were carefully sampled and tested to determine their physical characteristics, and, in addition, test specimens of the concrete and other pavement types were made up from the materials entering into the pavement.

On each 200-ft. section of concrete pavement or base the following test specimens were prepared: Three

slabs for determination of transverse strength, nine cylinders for compression strength test, and three slump test specimens. In order to duplicate as nearly as possible the actual conditions of construction, concrete for these specimens was taken from batches during the run of the day's work.

It is planned to leave the concrete slabs buried in the road shoulders until the section represented is tested by artificial traffic. The slab will at that time be removed to the laboratory and broken on a Riehle testing machine to determine the maximum transverse strength. The slabs are, for the most part, of Portland cement concrete, varying only in mix and aggregates with the sections they accompany. In special sections test pieces were made so as to incorporate the features of the pavement, as monolithic brick, concrete with mesh reinforcing, concrete with an addition of calcium chloride, or concrete with asphaltic concrete surface.

One of the three cylinders buried with each slab is broken in the laboratory for maximum compression strength when four months old, the second after a period of eight months, and the third will be broken with the transverse slab at the time of testing the road.

### Bearing Power of Subgrade

In the study of bearing power of the subgrade an attempt was made to compare the bearing power of the soils under impact as well as static loads. Comparison of the bearing power just before the pavement was laid and at various times after pouring the concrete was also attempted. The points at which the bearing power determinations were made were located 20 ft. apart along the center line of the road on the completed subgrade, and after the pavements were laid the determinations were made through the testing cylinders, which will be described later.

The impact determinations were made with the Goldbeck apparatus, shown in Fig. 1. The apparatus consists of a steel footing, 7 sq. in. in base area, into which is fitted a  $\frac{1}{2}$ -in. steel rod about  $3\frac{1}{2}$  ft. long. On the rod, fitted loosely so that it can be dropped from any height, is a steel cylinder of 10 lb. weight. The impact can be varied by dropping this weight from different heights. The depth of penetration is measured from a string stretched tightly between two steel rods driven firmly into the ground and set 2 ft. apart. On this string, which just clears the side of the rod, is suspended a small level. After any number of drops of the weight the distances are measured from the string to a given point on the rod with a 6-in. engineer's scale, and are recorded to one one-hundredth of an inch.

### Static Load Determinations

A special apparatus for making the static load determinations has been designed by the Illinois Highway Division. As shown in Fig. 2, this apparatus consists of a three-legged iron pipe frame from which is suspended a Toledo automatic hanging scale supporting a pail which contains about 30 lb. of shot. The load is applied to the subgrade by means of a  $\frac{1}{2}$ -in. steel rod terminating in a shoe  $\frac{1}{2}$  in. in diameter on the bottom tapered back to  $\frac{3}{8}$  in.  $\frac{1}{8}$  in. above the bottom. On the top of this rod is a pan which receives the shot from the pail which hangs on the scale, described above. An Ames dial, connected to the frame, with its plunger resting on the support attached to the  $\frac{1}{2}$ -in. rod, measures the depth of penetration as well as any upward movement of the rod due to elasticity of the soil. A thumb screw set in the frame enables the operator to stop the rod at will. At the 20-ft. distances on the center

Fig. 3 (Left)—Repeated load testing machine. Fig. 4 (Right)—Subgrade testing cylinder

line of the road an initial reading was taken with the footing resting on the subgrade without any load, after which the shot was released and readings were taken for total loads of 10, 20 and 30 lb. Additional readings were taken for two minutes at intervals of thirty seconds under the 30-lb. load. The load was then removed and the upward movement of the rod, due to the elasticity of the soil, was measured. The 30-lb. load delivered a weight of 150 lb. per square inch to the subgrade. To determine the bearing power after the pavement had been laid, measurements of the penetration under static load were taken through the testing cylinders set in the pavement as well as at points 50 ft. apart along the edge of the pavement.

### Behavior of Soils Under Repeated Loads

In addition to the observations made for determining the bearing power of the subgrade when subjected to static and impact loads, it is desired to know the effect produced by a load application which more nearly approximates the actual conditions brought to the subgrade when a truck wheel passes over a rigid surface.

From observations made November, 1920, on 7-in. surfaces it was indicated that the influence of an 8000-lb. wheel load was felt through a distance of 17 ft. on each side of the wheel. This would mean that the pressure produced at any point by a truck running at a moderate rate of speed would increase from zero to the maximum pressure in about one second, and decrease from the maximum to zero in the next second. The repeating load machine, which is shown in Fig. 3, was designed to approximate the above condition. The apparatus consists of a pipe frame in which are mounted a cam and spring for producing pressure and a plunger through which this pressure is delivered to the soil. The cam is driven by a  $1/16$ -hp. electric motor.

By means of a scale along which a pointer on the spring moves, any desired pressure is registered. The

Fig. 5—Determining deflection of concrete slab with subsoil excavated

Fig. 6—Apparatus for determining deflection of road slabs due to temperature and load changes

cam revolves at a rate which will produce ten applications per minute. The movement of the plunger, which is identical with the movement of the soil under the pressure, is shown by an Ames dial. A second Ames dial is used to regulate the machine so as to keep the pressure constant. The different footings, as shown in the illustration, range in area from 1 to 10 sq. in. The effect produced upon a soil by these repeated loadings is assumed to be very much like that produced upon a subgrade when a number of trucks travel over a rigid surface. It is supposed, therefore, that the behavior of the soil under the plunger will be very much like that of the subgrade under a load. By means of this apparatus the data can be secured on the action of the soils of different densities and moisture contents when subject to repeated loads. To obtain some light on the effect of applying loads on areas of different sizes the different footings are used. These footings are loaded from 10 to 50 lb. per square inch, the loads being varied by means of an adjusting screw at the top of the frame.

#### Subgrade Testing Cylinder

The special subgrade testing cylinder, shown in Fig. 4, has been designed for study of the relative movements of the slab and subgrade. When the last of the cylinders have been set there will be approximately 800 of them in use. They consist of a  $1\frac{1}{2} \times 1\frac{1}{4}$ -in. black iron reducer, A; a short length of  $1\frac{1}{4}$ -in. black iron pipe, B; a  $\frac{1}{2} \times 1\frac{1}{4}$ -in. brass disk, D; a short sleeve of 1-in. black iron pipe, E, and a special  $\frac{1}{4} \times 1\frac{1}{4}$ -in. brass bearing plug, F. Reducer, A, is flush with the top of the pavement and disk, D, rests freely on the subgrade. The length of the pipe, B, and sleeve, E, vary with the thickness of the pavement in which the cylinders are used.

In the concrete sections these cylinders were installed when the pavement was constructed. In the bituminous concrete and brick pavements they were installed after construction of the pavement by boring holes with a Calyx core drill and grouting around them with care so as to assure satisfactory contact with the adjacent pavement.

The brass bearing disk, D, follows the downward movement of the pavement and the upward movement of the subgrade, so that any separation between the subgrade and the bottom of the pavement, due either to rutting caused by traffic or occasioned by moisture or

frost conditions, can be learned by measurements taken from this plug.

The device for reading the change in position of the bearing plug in relation to the pavement is shown very clearly in the illustration. It consists of an Ames dial fastened in a support, C, which rests on the stationary brass disk, F, and a rod, G, which fits into a small circular depression in the center of the bearing plug, D.

The difference between initial readings taken as soon as possible after the testing cylinders are placed and readings taken at subsequent time show any change in position between the subgrade and the pavement.

These bearing plugs can also be used to obtain data on bearing power of subgrade by loading them with the plunger of the static bearing power determinator.

By removing the brass bearing plug and iron sleeve these cylinders afford an excellent means of obtaining subgrade samples for moisture content determination. Also the brass bearing plugs in the cylinders give excellent points for taking precise levels so that the amount of heaving or settling can be determined.

The testing cylinders are set in rows of three and five across the pavement, the rows being 25 ft. apart. When five cylinders are set in a row they are placed in the center, at the quarter points, and 18 in. from the edges, and when three are used, the ones at the quarter points are omitted.

#### Slab Deflection Tests

For obtaining data on deflection of the various sections when subjected to different temperatures, as well as to repeated loads, eight Ames dials are set on any slab. Two dials are independently supported, while five are set in a beam which rests on two supports, one placed on the shoulder and the other placed in the subgrade through a hole in the center of the slab. Two thermometers are used, one for recording the air temperature and the other for obtaining the temperature of the concrete. Four sets of observations are made on each slab. In the first set of observations, which is made for determining the effects of change of temperature only, readings are taken on the thermometers and dials every half hour for 12 hr. In the second set of observations, taken for the purpose of determining the deflection caused by loads applied to the corners of the slabs, readings are taken for 24 hr. at half-hour intervals. From 4000 to 6000 lb. is applied at the corner

every hour. A reading is taken and the load is immediately released. One-half hour later a reading is taken without the load. The results obtained already show that the measurement of the load deflection would be futile without the determinations of temperature changes, because the warping of the surface, due to temperature variations, greatly exceeds the deflection under the loads applied.

#### Effect of Subgrade on Slab Deflection

For the purpose of securing some idea of the effect of the supporting power of the subgrade on the deflection of the slab after the 24-hr. run the subgrade is excavated under the corner (shown in Fig. 5) and several observations are made to determine the difference in the deflection of the slab when supported and when not supported by the subgrade. During the loading tests a strain gage is set along the diagonal for the purpose of securing some idea of the deflection of the upper surface. For the first 12 hr. of the loading run the dials are set along the diagonal 0—1 and for the second 12 hr. along the diagonal 0—2. This work is carried on by a corps of engineers divided into three shifts, each working 8 hr.,

so that continuous readings are made day and night.

For determining the distribution of loads across joints and through pavement slabs of different thicknesses and types, soil pressure cells are placed under corners and centers of the slabs, and two Ames dials are set—one on each side of the joint about 2 in. from the edge of the pavement. The apparatus is shown in Fig. 6. A thermometer is supplied for registering air temperature. After the apparatus has been set up a loaded truck is brought slowly toward the point with its outer wheel about 6 in. from the edge of the pavement. The truck is stopped as soon as the dials give the first indication of the deflection of the pavement. Readings on the dials and the pressure cells are then taken, stopping the truck every 2 ft. to the joint and every 2 ft. beyond the joint until the dials again indicate that the truck is so far away as to cause no deflection. Because of the warping action of the slab and the temperature change, these readings are made at night as well as day, the daylight readings being taken between 9 a. m. and 4 p. m., and the second set the same day between 9 p. m. and 4 a. m. Especial attention is given to securing definite time intervals for each loading.

## Some New Automotive Equipment

### A New Fuel Vaporizer

A FUEL vaporizer designed to separate from the air stream liquid particles of fuel passing from carburetor to engine, convert these into a gas and again introduce them to the air stream, is shown in the accompanying diagrammatic sketch. Wet fuel mixture from the carburetor enters the central separating chamber through the Venturi tube at the right. The lower ve-

Diagrammatic view of Mitchel vaporizer

locity in the separating chamber and the change in direction of the air stream results in deposition of liquid fuel particles on the exhaust heated walls of this chamber. Portions of the fuel not vaporized by the wall contact are drained by gravity into the pipe coil which passes through the exhaust jacket and terminates in an annular space around the throat of the Venturi, whence the fuel vaporized in the heating coil again issues into the air stream and passes to the engine through the top outlet of the separating chamber.

The device has been developed by G. I. Mitchel.

### Chassis Lubricator

A MULTIPLE oiler for lubricating chassis parts is manufactured by the Manzel Brothers Company. It comprises a number of pumping units equal to the number of places to be oiled, which are assembled in the

oil reservoir and from which leads run to the bearings to be lubricated. The pumping units are operated by means of a pullrod extending through the dash and instrument board, the oil reservoir being mounted under the hood. From the reservoir connections are made to all the points on the chassis requiring lubrication. The system enables the driver to lubricate every bearing while sitting at the wheel, either while driving or while standing in the garage. The system can be supplied for any chassis and with any number of leads.

PISTON rings with packing material have proved very satisfactory in different kinds of machinery, and the German automobile engineer, Hanfland, proposes for use in automotive engines piston rings that have an annular groove on the outside which is filled with an oil-absorbing, heat-proof material, say a graphite composition.

Manzel chassis lubricator

# British Air Ministry to Analyze Engine Development

Information regarding prevalent causes of failures will be particularly sought for. Number of researches will be carried out at universities. Future development to proceed with a multi-cylinder high compression engine. Aeronautical Research Committee reports on past experiences.

**I**N the annual report of the Aeronautical Research Committee for the year 1920-21, recently published, the work of the Engine Subcommittee is reviewed. Research work under the supervision of this committee was carried on at the Royal Aircraft Establishment, the National Physical Laboratory and the Air Ministry Laboratory at South Kensington. At the R. A. E. particular attention was paid to general problems affecting routine testing, as well as to some special problems, such as those connected with work on high flash point fuels, direct injection and ignition. At the N. P. L. a lengthy research on detonation was begun on lines laid down by Sir Dugald Clerk. Certain questions that came up were referred by the Director of Research to the Air Ministry Laboratory, such as a research concerning the present status of the internal combustion turbine and experiments on engines and air flow meters.

In developing a program of research the Engine Subcommittee kept in mind the urgent need for greater reliability in engines and power plants of aircraft. In this connection an analysis is being made of a large number of engine failures. For future development it has been decided to proceed with a multi-cylinder, high-compression engine, to discuss the design of an engine developing high power at altitude, to consider the possibilities of a high-speed aircraft engine and to investigate the use of high boiling liquids and water under pressure as cooling media.

## Analysis of Engine Failures

It is proposed in the report that the Air Ministry analyze and issue in collected form, for the information of engine constructors, their experience as users of engines as regards points affecting reliability, and to arrange for continuing to do so in the future. Information regarding epidemic causes of failure which have occurred in the past should be collected in particular. The Air Ministry was asked to carry out reliability trials with various types of engines, which, in case no British engines of the type were available, would be of German manufacture. In accordance with this request, tests are now being carried out on four German engines of two types supplied by the R. A. F., the tests being those specified by the Air Ministry for new British designs.

A series of experiments on the effect of pressure and temperature on the occurrence of detonation are also in contemplation. Detonation has been experienced in the small tube between the explosion chamber and the recording diaphragm, but this has been overcome by placing the latter in the surface of the experimental vessel. This experience raises the interesting question whether detonation in a restricted volume, such as a small pocket at the spark plug, is a cause of detonation in the vessel, and this matter will be investigated. The

effect of turbulence on detonation will be investigated by the N. P. L., a small fan being placed inside the cylinder; also the effect of adding oxygen to the air of the mixture until a point is reached where detonation occurs. Mr. Ricardo, in a paper submitted to the committee, drew attention to the small amount of inert gas which is required to check detonation; he believes that 5 per cent of such gas is sufficient to enable a compression ratio of 5:1 to be increased to 6:1, while at the same time increasing the thermal efficiency from 31 to 33 per cent. Mr. Ricardo also expressed the opinion that prolonged detonation is liable to cause crystallization in engine cylinders, a matter which he plans to investigate further.

## Accurate Air-Flow Meter

A report has been made to the committee on the Calender air-flow meter, which has been developed at the Air Ministry Laboratory at South Kensington. By means of an electrical method the instrument records the mean air flow through a tube, and it could readily be adapted to record the flow through an engine inlet pipe. Its chief advantage would reside in the possibility of its use for estimating the performance of engines at high altitudes. According to a further report on this flow meter, it was found to give an accurate measurement in all cases except when the flow reversed.

In connection with high-compression, supercharge engines, the question of variable valve timing is of interest. A delay in the closing of the inlet valve gives a lighter charge with a lesser chance of detonation. The use of the device for ground level control gives an estimated increase of 15 per cent in the available power and an increase of 7 per cent in fuel economy at half load at ground level. So far all experiments along this line have been made on a single-cylinder engine, but for the future experiments with a modified form of some existing aircraft engine, such as the Semi-Sikh, are contemplated.

## Factors Causing Vibration

In response to matters suggested by the Director of Research, it is stated that it is at present very difficult to formulate rules for avoiding synchronous vibration in engines, but that it is possible to calculate from the completed design whether synchronism will occur or not. It is uncertain whether engines can be always installed in planes so as to avoid serious vibration. In connection with these problems a comparison of torque reactions in different types of engines has been drawn up.

Considerable attention has been given to the subject of the magneto, with special reference to the problem of eliminating trouble due to sparking across the safety gap at high altitudes and to the question of the compara-

tive qualities of British and German magnetos. The former arises through the safety gap sparking voltage, decreasing more rapidly than the spark plug voltage with reduced pressure. A contributing cause probably is the cooling of the cylinder, due to shutting off at high altitudes. The most serious case of sparking at the safety gap occurs in engines with super-compression, in which the compression pressure is maintained regardless of the altitude. Various solutions of this problem have been suggested, but nothing definite has yet been arrived at.

#### Tests with Induction Type Magneto

In an investigation previously reported it was shown that the optimum results from an inductor type of magneto with a shunted resistance were obtained by reducing the number of secondary turns from the standard 10,000 to 7000, the sparking performance with a shunted resistance being increased from 45 to 60 per cent by

this means. The observations have now been extended to a rotating armature magneto (Bosch DU-4), and the results show that the optimum number of secondary turns is 7200, as against the standard, 8400; the average increase in performance was 11 per cent, while the shape of the low-speed characteristic was practically unaltered. The shunted secondary capacity characteristics showed an increase in performance of 12 per cent.

During the coming year a certain number of researches are to be carried out at universities, and in this connection consideration has been given to various designs of test bed. The Ricardo unit proved the most useful and was recommended by the committee. For other work the R. A. E. is developing a design of universal test bed suitable for the fitting of different types and sizes of cylinder.

A new altitude test chamber is to be constructed, as the existing plant at the R. A. E. is inadequate to test present-day engines with satisfactory results.

## New Fiat Racer in Italian Grand Prix

IN the Italian Grand Prix race, briefly reported in our Sept. 8 issue, a new design of racing car due to the Fiat company of Turin made its initial public appearance. These cars are fitted with eight-cylinder-in-line engines of 65 by 112 mm. (2.56 x 4.41 in.) bore and stroke. A sheet steel water jacket surrounds each group of four cylinders. There are two valves inclined in the head, the spark plug is in the center and two separate camshafts are used, the drive being at the rear by means of a vertical shaft. By means of bevel gearing this shaft also drives two four-cylinder magnetos.

One of the features of this engine is the extensive use of roller bearings, the crankshaft being carried in ten bearings of this type. Roller bearings are also used for the connecting rod ends and for the valve operating gear. Lubrication is under pressure with a dry sump. The engine is mounted directly in the frame by four points and has the gearbox housing bolted up to its rear. Water is circulated by means of a pump, and a draught of cold air is directed through the crankcase. Maximum power is developed at about 4300 r.p.m., when it is believed that the engine gives off about 112 hp. No authentic information has been given out on this point, but it is known that the engine will run up under load to 4600 r.p.m.

Both drive and torque are taken through the springs, which are underslung semi-elliptics. The gear ratio used in the race was 14-52, compared with 14-45 for the Ballots, both with 33 x 5-in. tires. Brakes are applied simultaneously on all four wheels, the drums in front being rather smaller than those on the rear. Fabric lining is used in front and cast iron at the rear.

All cars in the race used the new Pirelli straight-side cord tire of 33 x 5 in. Ralph De Palma started out without a spare, but the others carried one wheel at the rear. The big straight sides making the cars rather heavy to steer, Goux decided to use Pirelli clincher-bead, 32 x 4-in. tires on the front, these being of fabric construction. Wagner tried this combination in practice, but after he had lost a tire off the rim at more than 100 miles an hour, he considered it unsafe. The service given by Pirellis on the Ballot cars was excellent, the two leading cars finishing with their tires in condition to run, doubtless, another couple of hundred miles. The Fiat drivers, particularly Wagner, had many tire stops, and it was claimed that the reason the Pirellis did not stand up so well on the Fiats was their higher center

of gravity. This is denied by the Fiat engineers, who claim that the difference in this respect is not more than an inch. The Ballot frames are 14¼ in. from the ground and the Fiats 15 7/16 in.

The winning Ballot cars are the machines which ran in the French Grand Prix at Le Mans. De Palma had the car with which he ran at Indianapolis.

## African Automobile Trade

A WRITER in the London *Times* Trade Supplement cites Nigeria and the Gold Coast as places where local conditions impose big difficulties on British automobile truck makers to fit in with their special local requirements. As regards Nigeria he says: "At present vehicles using the more heavily metalled Nigerian roads must be fitted with rubber tires of a width of not less than the number of inches equal to the number of half tons of registered axle weight. No axle weight may exceed 4 tons, and the total axle weights of a vehicle must not exceed 5½ British tons (12,320 lb.). If the vehicle is used at all on light-metalled or clay surfaced roads, it must be fitted with air tires on all wheels."

Moreover, a change in the law as from the beginning of 1923 provides that only air tires may be used on any of the roads and that no vehicle may be fitted with double tires. This regulation he thinks will compel the use of giant air tires on all but the lightest vehicles.

As to the Gold Coast situation, there the gross weight of a vehicle, including driver and passengers, must not exceed 2½ British tons (5600 lb.), though exceptions may be allowed by district commissioners.

Consequently local buyers are justified in placing orders for automobiles with makers who act in response to, and even in anticipation of these restrictions, and who design their automobiles accordingly to meet the largest needs of the greatest number of export markets. It is precisely because American automobiles embody these features that they now hold markets, as well as making others, to which on national grounds they have no such prescriptive title as the Britisher.

THE President of Peru has submitted a law to the Chamber of Deputies providing for the nationalization of all petroleum deposits found in the country. Recent investigations have produced results showing the presence of extensive deposits of oil.

# Precision Machine Work in the Production of Aluminum Pistons

Methods employed in manufacturing pistons for the Essex engine. Special care exercised in machining the piston pin hole square with piston axis, and in aligning piston with cylinder bore.

By J. Edward Schipper

**A** NEW piston has recently been adopted for the Essex automobile which is not only interesting from a design standpoint, but presents some special manufacturing considerations which are unique. The entire layout for manufacturing this piston has been arranged in the belief that piston wear, oil pumping and failure of the piston rings to properly engage the cylinder bore are due in a large measure to misalignment. This misalignment causes tilting, or what is known in shop parlance as cocking of the piston in the cylinder, and results in one side of the piston acting as an oil scraper, thus giving unequal lubrication around the cylinder walls. The rings also tend to rotate and make it difficult or impossible to secure a good seal.

The pistons are manufactured from Lynite aluminum alloy. They are permanent mold castings and weigh 20 oz. before machining. The finished piston averages 13.5 oz. in weight, hence 6.5 oz. of metal is cut from each piston. The manufacturing schedule is based on the production of 550 pistons per day, so that the piston department machines off slightly more than 223 lb. of aluminum per day.

In following through the chain of operations necessary to complete an Essex piston the point which should be borne in mind is that in every operation where the consideration enters as a factor at all, parallel alignment of the piston pin hole with the head of the piston is very carefully maintained, as well as squareness of the piston pin hole with the vertical axis of the piston.

The first operation is to bore the open end of the piston. An unusual method of centering is employed in this operation. The centering tool comes in from the back of the No. 2 Warner & Swasey screw machine through the chuck and cuts a center in the projection

which is left on the center of the piston head for the purpose. The location is so arranged that the center mark must align itself exactly with the center of the open end of the piston. The latter piston is centered on a cone guide, which is exactly concentric with the centering tool. After centering, the open end is bored.

A Fay automatic lathe is used for turning the outside diameter and facing the end of the piston. This same machine also rough cuts and finish cuts the ring grooves. The finish is a sort of sizing or burnish which gives a mirror finish. For this work the piston is located from the open end, which was bored on the first operation, and from the center, which was cut on the piston head. This machine is the fundamental factor in timing the operations all through the department, as its capacity is 60 per hour, which is less than any other of the operations performed. The finished ring grooves on this machine are held to a tolerance limit of  $\pm .0005$  in., — 0.

The piston head is faced and the fourth piston ring land is undercut in the next operation. The fourth piston pin land is undercut to allow the ring to project .0125 in. on each side, or, in other words, the total diameter of the fourth piston pin land is .025 in. less than the diameter of the other land. This allows the lower ring to act as an oil scraper. The work is done on a Porter cable lathe, and the location is from the open end of the piston and from the center. The work revolves in this operation and is driven by a pin on the cone seat which bears against the piston pin boss.

One of the most interesting operations in the manufacture of the piston is the cross-boring, which is done with great care in a pot-chuck on a No. 4 Warner & Swasey turret lathe or screw machine. The pot-chuck is so arranged that the location is from the flat of the piston head to give the proper distance from this flat surface to the center line of the piston pin hole. The alignment in reference to the bosses is made sure by first inserting a lining bar which enters the cored hole. The next tool which comes into operation is a boring drill and the third a piloted, single-cutter boring tool, which takes a truing cut and gives an accurate alignment of the hole. The next tool on the turret is a floating reamer which accurately sizes the holes, after which another tool cuts two pin-retaining grooves in the piston pin bosses. On this machine the work revolves and the tools are piloted on both sides, this being accomplished by a pilot in the jig on the far end and pilot bushing on the near end which enters the hole and acts as a pilot bearing for the tool. For lubrication on making this cut, and a great majority of the cuts throughout the manufacture of this piston, a mixture of kerosene and so-called mineral "lard" oil is employed. This has

Finished Essex piston and blank from which it is made. The finished piston weighs 13.5 oz. and the blank casting 20 oz.

1—Boring open end of piston and establishing center. 2—Turning overall diameter and facing end of piston on a Fay automatic lathe. This same machine also rough and finish cuts the ring groove. 3—Facing the piston head and under-cutting the lower piston ring land. 4—Cross-boring the piston in a pot-chuck with special provisions for accuracy in boring by piloting the tools. 5—Hand reaming the piston pin hole after cross-boring operation has been completed. 6—Sawing a  $\frac{1}{4}$  in. slot under the bottom piston ring. Note simple locating method in V-block. 7—Drilling twelve oil holes in the piston skirt on an indexing fixture which takes care of spacing as well as stagger

been found to assist in giving a very clean surface. The work is held to as close limits as possible on this machine, but in order to meet the tolerances required the piston pin hole is hand-reamed after the machine operations are completed. This hole is held to plus or minus .0003 in. The nominal diameter is .875 in.

A 3/16-in. slot is sawed under the bottom piston ring. For this operation the piston drops over a dowel pin, which passes through the piston pin hole and into a V locating block. No clamp is necessary to hold the piston in this jig, as the action of the saw, which is downward, tends to force the piston directly into the V block. The saw has a capacity of 200 pistons per hour.

There are twelve oil holes in the piston skirt, each 3/32 in. in diameter. The holes are equally spaced circumferentially about the piston, but are staggered in an axial direction. This work is accomplished on a Leland Gifford drill, to which is fitted an indexing fixture which rotates the piston in the jig and spaces the holes properly. To take care of the stagger in the holes the fixture brings the work back and forth by means of a cam. The pistons are held in position on a spring clamp, which allows the cam to move the work back and forth, taking care of the staggering of the holes. The fixture is foot-operated and one machine can easily take care of 200 per hour.

There are also two oil holes which lead oil to the wrist pin boss. These holes are inclined at an angle of 50 deg. to the vertical and require an indexing fixture, which permits the drill to operate vertically, the work being inclined at the proper angle.

The location of the work in the fixture is from the piston pin hole by means of a locating pin which passes through the holes. These are 1/8-in. holes, and the machine has a capacity of 100 per hour. The machine used is a Sipp drill. Another Sipp drill is used for chamfering the wrist pin hole to break the corner at this point and to prevent a burr in assembly.

### Grinding Operations

For grinding the piston pin boss relief a Landis grinder is employed. The work is located by the open end of the piston against a cone seat with a driver fitting closely between the piston pin bosses. A special cam brings the work in contact with the grinding wheel at the four points at which the relief grind is taken; that is, one point on each side of each extremity of the piston pin boss. The machine readily takes care of 150 pistons per hour.

The same type of Landis grinder is used for rough grinding the outside diameter. This is a 6 x 18-in. machine, which takes off a roughing cut of .012 in. per side, leaving for a finish grind .0015 in. on each side. The rough grinding operation is taken care of at the rate of 100 per hour.

Particular care is taken in the finish grinding to hold the temperature of the cooling system for the machine within the desired range. It was found, in checking up the piston diameter, that a considerable temperature variation in the cooling system, such as might be experienced in cold weather, caused a variation in the diameters of the pistons turned out in the morning and later in the day, when the temperature was higher. In order to overcome this the temperature of the cooling medium is held at between 65 to 70 deg. Fahr. in order that more metal is not ground off on a warm day than is taken off on a cold day. The wheel used for finish grinding is a 36-L crystolon, this being a Norton wheel, and is the same wheel used for the rough grind. The relief grinding is done with a No. 24 CL Alundum wheel.

The range of variation in the cylinder bore is .002 in.

by steps of .0005 in., which is the machining limit on each size. The piston sizes, which are arranged for selective assembly, are seven in number and fit within this range. The nominal outside diameter of the piston is 3.372 in., with a variation of +.0015 in. and -.0005 in. Within this .002-in. limit there are seven selections for assembly, and the pistons are gaged and marked in accord with this. The machine used for gaging the pistons is the ordinary type of amplifying gage, which is checked up with a master plug, and the symbol for size is a letter stamped on the piston after gaging. The operator on the finish grinding machine is also provided with an amplifying gage for checking outside diameter for size and roundness before the piston goes to the inspection department.

### The Final Cuts

Following the finish grinding and inspection, the center is faced off on a Sipp drill. A final cut is then taken on the piston pin hole and the diameter checked with a go and no-go gage. The limits of the piston pin are shown by the diameters of the gage, which are .8747 on the go side and .8753 on the no-go side. This final cut is a hand-reaming operation, the ream being power-driven and the work hand-held. This differs from the former hand-reaming operation only in that the ream is driven at 60 r.p.m., whereas the first hand-ream had a reamer speed of 80 r.p.m.

At this point a line is drawn through the piston center line on the piston head. This line is drawn by means of an eccentric and a plug through the piston pin hole. The eccentric brings the piston down against the face plate, and the center line is then drawn on the top of the piston parallel with the axis of the piston pin hole. The purpose of this is for lining up in assembly with the connecting rod.

The skirt of the piston is split by means of a 1/16-in. saw-cut. The slot cut in the skirt is on an angle so that the slot does not work vertically up and down in the cylinder, but has a sliding action.

For checking the piston head and the accuracy of the cross-bore, a special inspection gage is employed which has amplifying gages in which the indicator points are run around the circumference of the piston head and also on a mandrel which passes through the piston pin holes. The amplifying gage is checked against the mandrel on one side, and the piston turns around 180 deg. and the amplifying gage then checks on the other side of the mandrel, which gives accurately any misalignments in the piston pin hole. Each of the pistons is stamped with the weight, which is necessary in the selective assembly.

An interesting phase in the assembly of the pistons, which is really a check on the piston itself, is the piston aligning fixture, which is bolted to the crankcase on the crankcase assembly line. It is in this aligning fixture that the line on the top of the piston is used. The fixture is so arranged that it has a gage with two high points, both of which must touch the piston head. If one touches and the other does not, the connecting rod is brought up to perfect alignment, so that both of the high spots on the aligning fixture will touch. The center line drawn on top of the piston must then also be parallel with the line on the aligning fixture.

Inasmuch as this fixture goes directly on the crankcase itself and is a part of the assembly operation of the engine, it gives a final check-up on the alignment of the piston and makes it certain that the piston will be operating on a true axis. This is the final step and illustrates the care given to avoid tilting of the piston in the bore.

8—Drilling two oil holes for the wrist pin. These holes are inclined at an angle of 50 deg. to the vertical. 9—Grinding the piston pin boss relief on a Landis grinder. 10—Grinding outside diameter of piston. 11—Amplifying gage and master plug used for checking same employed in piston inspection. 12—Drawing center line on piston head in a special jig. 13—Inspection gage for checking squareness of head and piston bore. 14—Aligning jig which is fastened to the crankcase to check up on squareness of piston. The center line is checked against a straight edge on the jig as illustrated, to make piston float freely

# Motor Bus Problem Discussed at Electric Railway Convention

Conservative traction interests apparently regard bus lines as competitors rather than as possible aids in solving transportation problems. It is evident, however, that the most economic means of transportation will survive in any given case. Mutually profitable cooperation is possible.

By Sinclair Gluck\*

**T**HE fortieth annual convention of the American Electric Railway Association at Atlantic City, October 3 to 6, has come and gone. And any interest at the convention in a comprehensive solution of the problem of motor bus competition was conspicuous by its absence.

Allusions to bus competition in many of the speeches showed clearly that members consider it a danger rather than a possible ally. But no attempt was made to face the issue directly.

There were two elements present. One side, the more conservative, was greatly in the majority. These men seemed to regard the bus as a menace to their business and nothing more.

The other and more progressive side, consisting of only a few men, some of whom have already installed buses to co-operate with their trolleys, regarded the bus not only as a possible but as an actual ally. But these men made no headway against the weight of opinion ranked against them.

Taking the convention as a whole, the motor bus may be said to have been almost entirely disregarded as a factor in street car line transportation.

If it were possible to get a birdseye view of any extensive modern movement or improvement, from its inception to its final stage, the slow and ponderous nature of the development—the innumerable bypaths and costly blunders which accompanied this development—would be strikingly apparent. Single individuals or even small groups of men have dreamed a dream and seen a vision that has taken them almost directly to the final goal. But give the movement a broader scope and the wastage of time and misdirected effort often becomes appalling.

Passenger transportation in the United States has been no exception, principally because, aside from the steam railroad, the development of passenger transportation has been in the hands of many individuals, working locally, and with little idea of what the other fellow is doing or why he is doing it. Few have been able to profit by the blunders of others and still fewer to take advantage of the successes of others.

## Little Effort to Solve Problem

There are organized and influential groups of men in the passenger transportation business, aside from the steam railroads. There are the electric railway interests and there are the manufacturers of buses and of truck chassis convertible into buses. But it is necessary for both of these important groups to work in a fundamentally con-

structive way to solve the short haul passenger transportation problem.

There was little effort along this line at the annual convention of the American Electric Railway Association. Men in the transportation business—men of vision who say beyond the immediate sale of their commodity, to a market better, broader and more satisfactory to all concerned—may have held great hopes in this convention. But their hopes were justified to a very limited extent.

Passenger transportation in short haul work in the United States is in a chaotic state of flux at the present time. Here and there, in cities such as New York, Washington and Toledo, well organized, efficiently operated motor bus lines are working in conjunction with street car lines to a greater profit of both and the general satisfaction of the public. Here and there in other cities more or less well organized bus lines are competing with street cars at a profit to themselves and a heavy loss to the electric lines. Here and there jitneys operated on a shoe string are cutting down the number of street car patrons at little profit to themselves. Elsewhere buses have tried to compete and have failed. The difference in the outcome has depended upon local conditions and the efficiency with which each type of transportation was organized and operated.

There can be no doubt in the mind of the intelligent observer that there is a field for short-haul bus transportation. And there should be no doubt in his mind that the bus is to be reckoned with in that field.

At the convention the electric railway interests apparently regarded the bus as a powerful and threatening factor. And the bus was regarded so far as most of the set speeches were concerned, as an opponent only—not a possible ally.

On the whole, the attitude of the speakers somewhat resembled the King Canute point of view. The more conservative electric traction interests do not want the tide of bus competition to rise any higher. So it seemed to be generally conceded that the best thing to do was to order it back, by means of legislation and of a great publicity campaign, extolling the benefits of street car lines to municipalities and the general public, and decrying buses as undependable, incapable of handling the traffic and unwilling or unable to stand their share of municipal duties and municipal taxation.

One speaker stated that there was only one successful bus line in the United States, the Fifth Avenue Coach Co.

Another stated that no bus line stood its share of municipal expenses.

\*Managing Editor *The Commercial Vehicle*.

There are many successful bus lines in California and elsewhere. Bus lines pay taxes and in some cases have franchises. And the work of the Fifth Avenue Coach Co. in clearing the snow during the last two winters from the streets on which it operates was an excellent example to municipalities far and wide.

**But far more important than any inaccuracy of statement was the mistaken attitude of the convention toward the entire problem. After all, it is the most economical form of transportation which should—and will—survive. The question, fundamentally, is not one of profit for traction companies now in business and in no hurry to go out of business, but one of solving the problem of the most economical and efficient form of transportation in each locality and under each set of conditions.**

Either the street car lines are of real and permanent value to the communities in which they operate, or they are not. If they are of permanent value they will survive and they have little to fear, except possibly financial mismanagement and inefficient operation. If they are not of real and permanent value in their particular communities, the directors and stockholders should read the writing on the wall and either get out of a bad business altogether or adopt the type of transportation which will solve the problem in their communities—for if they are not of real and permanent value, *they will not survive.*

#### Committee Report Not Ready

Some of the electric railway interests have realized the importance of a clear understanding of bus transportation. A committee of fourteen had been previously appointed, under the chairmanship of H. B. Flowers, vice-president of the United Railways & Electric Co. of Baltimore, to inquire into the question of trackless transportation. Unfortunately, the committee had not sufficient time to prepare a comprehensive report.

At the general meeting on Wednesday, October 5, in the morning, Mr. Flowers, the committee chairman, announced that he had only a progress report to make. He asked that the committee be reappointed further to consider the question of trackless transportation. He stated as his view that the trackless trolley and the motor bus must be conceded a place in the sun and that more time should be granted the committee to inquire further into this important subject.

It has been stated that of the fourteen reports of sub-committees which should have been turned into the committee, only two were available in time for the convention. One of these, the report of the sub-committee representing motor bus manufacturers, was turned in to the committee. No notice was taken of this report on the floor of the convention.

The two members of the committee, F. W. Fenn of the National Automobile Chamber of Commerce, and D. C. Fenner of the International Motor Co., who represented this sub-committee, were present at this session with a recommendation which they had prepared dealing with the manufacturer's angle on trackless transportation.

The report of the committee on publicity called attention to the failure of buses to handle the traffic in Des Moines when street car lines were discontinued. There were numerous leaflets available dealing with the Des Moines situation and attacking the bus generally.

#### Competition Felt

F. E. Frothingham, of Coffin & Burr, Boston, Mass., stated that the street car lines have been subjected to severe competition in the jitney and in bus lines. This was badly met. The street car lines ridiculed it instead of in-

sisting on fair competition and trying to absorb this competition. This attitude resulted in hostility from the public. He stated that the Fifth Avenue Coach Co. was the only successful bus line in the United States, and went on to say that possibly trackless trolleys might solve the problem of this competition for the street car line. But, he said, that if there must be competition, buses and jitneys must bear their share of street maintenance in clearing snow just as the street car lines do.

J. K. Newman, Isadore Newman & Sons, New Orleans, La., also spoke on the subject of street car line finance, municipal ownership, etc. He referred in passing to jitneys and buses. The gist of his remarks was as follows: Jitneys and buses take money from the street car lines. When this happens the street car lines have to raise their fares to meet expenses and the public suffers accordingly. If the street car lines are discontinued, he said, up will go the fares on the buses and down will go the service. It is not clear from the above why the public which takes the bus should suffer because the street car line raises its fare. And the question of increased fare and decreased service on the bus lines, once the street car lines are discontinued, is problematical to say the least.

Finally, he said, that as street car lines are discontinued the city will lose the franchise and the paving done by the street car lines. Jitneys and bus lines, he stated, should not be permitted in competition with trolley lines any more than two fire departments should be permitted. City franchises should guarantee no jitney or bus competition with street car lines.

Edwin Gruhl, vice-president and general manager of the North American Co., New York, in the course of his speech also touched on the subject of motor bus competition. He states that "While the motor bus has the advantage of low investment and small overhead expense, and greater speed and flexibility of operation, the operating cost of a motor bus per seat mile is practically twice that of an electric car. It is not likely, therefore, to seriously menace the industry except during periods of unemployment." According to a prominent bus operator these figures are based on the 16-passenger bus and do not apply to buses of larger capacity.

These remarks are characteristic of most of the speeches in which jitneys and motor buses were mentioned. But it must not be understood that all members of the American Railway Association are inclined to disregard the real value and importance of motor bus transportation. H. B. Flowers, general manager of the United Railways & Electric Co. of Baltimore, and chairman of the committee on trackless transportation, is very much in favor of the use of buses by street car lines. His company was one of the first to use buses, operating first twelve and then fifteen. The company is now going in for larger buses and may possibly experiment with double deckers.

In the debate on Tuesday J. P. Barnes, president of the Louisville Railway, led the progressive element. He said that the electric railway should regard itself as the transportation purveyor of the community, and as such should use every means available to improve transportation. He stated that the automotive industry was composed of real live men who knew the facts. In this connection he referred to the address last year in which Mr. Graham, coming from the automotive industry, held out open arms to the electric railways and offered to help them in any way possible. Mr. Barnes went on to say, "We took our heads out of the sand then, but we've stuck them back in again now."

**Unorganized jitney buses have done much in many communities to damage the prestige and decrease the profits of street car lines. If this is the case properly organized and efficiently operated bus lines**

will surely do more damage. And these bus lines are coming. Therefore, where bus lines are practicable it would seem obvious that there are only two courses of procedure open for the street car line in certain cases, either to organize and operate the inevitable bus lines themselves or go out of business.

From the views held by the representatives of manufacturers present at the convention it would seem that there is a strong inclination on their part to recommend the use of present standard equipment for buses.

#### Chassis Offers Problem

The attitude of the manufacturers is perfectly comprehensible. The exact specifications of the vehicle most suitable for city bus work have not yet been determined. It is not known what type of chassis will be demanded of them by the street railways which buy and operate buses nor is the extent of that demand known. To construct a chassis which will be ideal for city bus work will mean much research and designing effort and possibly the installation of additional machinery to manufacture the

final design. It is natural that the manufacturers are reluctant to undertake this work without any knowledge of the extent of the market on which they can depend for the sale of the ideal vehicle when it is completed.

On the other hand there are some who hold that the truck chassis is not suitable for the best type of city bus transportation. They hold that the high center of gravity increases the danger of overturn, also that the height of the body on the truck chassis makes it inconvenient for the passengers to board and alight from the vehicle. And there are other doubtful features. As an example of this it is reported that a truck chassis of a prominent and reliable make was recently tested out in city bus work by a large bus company. The bus had already made a trans-continental trip, but was in perfect condition and was driven by a representative of the manufacturers. At the end of a week the clutch, the brakes and other parts of the vehicle are reported to have failed under the constant strain of stopping and starting in traffic and the vehicle was practically useless.

But the bus is coming. The ideal type of bus chassis is coming also and will survive.

## S. A. E. Standards Work in Progress

**T**HE Society of Automotive Engineers has been requested to formulate a standard for wing nuts in order that designers may refer to a standard list and select sizes which may meet their requirements.

As it is recognized that the formation of such a standard should be based on the best present practice the S. A. E. is obtaining data on current practice for the different types of wing or thumb nuts and those standards which are in general use by small industrial groups such as bolt and nut manufacturers.

The adoption of a standard series of wing nuts will do much to decrease the cost of certain wing-nut sizes through greater production and will ultimately result in discontinuing many special sizes.

#### Makers May Standardize Clutch Facings

A. C. Bryan, vice-chairman of the Transmission Division, has submitted a preliminary recommendation for S. A. E. clutch facing standards based on present practice. This recommendation will be thoroughly discussed and, if possible, finally acted upon at the fall meeting of the Transmission Division.

It is believed advisable to divide the facing sizes into two divisions—one for single plate and the other for multiple plate clutches. The majority of single-plate clutches seem to be made in three sizes, 8, 10 and 12 in., and in view of the fact that they are quite similar in design and are housed by flywheels bored 8, 10 and 12 in. respectively, it would appear that a standard inside and outside diameter can be agreed upon without running into much opposition from the clutch makers, as these sizes will fit into their present clutches without any change in the design of the clutch parts.

A great number of multiple-disk clutches on the market are so varied in design that it makes the question of standard facing sizes for this type somewhat more difficult than in the single-plate clutch, but it is believed that the many sizes of facings now used can be reduced to a comparatively few if the matter is studied by the S. A. E.

It is generally recognized that one of the most effective ways of identifying stolen automobiles and minimizing the danger of their being stolen in the first place would be

the general adoption of a method of numbering engines which would make it impossible to change the numbers without leaving indications that a change had been made.

Replies to a letter from the S. A. E. Standards Department soliciting advice from automobile manufacturers on this problem indicated that the stamping of plain characters on several parts of the engine and other units of the chassis is the most satisfactory way of guarding against having the numbers changed by automobile thieves. It is realized, however, that if a simple means of numbering cast-iron or aluminum castings can be discovered which will make it difficult for the numbers to be changed, it would be a real solution to this problem. The suggestion has been made to the S. A. E. that a solution might be found by the casting of a special alloy block in the surface of that part of the engine casting which is to be numbered, the composition of the alloy being such that it would be impossible to change the numbers by any simple means. The selection of such a material would depend, of course, upon its physical characteristics. Members of the Iron and Steel Division have been asked to study the possibilities of this solution.

Any suggestions in this connection which might be developed into a satisfactory means for numbering engines should be referred to the Society.

## Tractors and Trucks in Morocco

**A**CCORDING to the French trade organ, *Exportateur Français*, there is a good scope at Morocco for tractors and trucks, a reason assigned being the absence of coal, and therefore lack of railroads.

The British Consul General at Beirut, Syria, pays a tribute to the enterprise of American auto firms in that territory. American cars, he says, greatly predominate because of being cheap, light and powerful to climb the stiff grades, whereas the cheaper British cars fail as hill-climbers, and dearer ones are either too expensive or too heavy. Trucks and vans, he says, have a good scope about Damascus and Beirut, where the merchants find it cheaper to use the roads in preference to the railway, the latter having inadequate carrying capacity.

# Bright Future Predicted for U. S. International Trade

Speakers at American Manufacturers Export Association believe exchange situation will be remedied slowly but surely. Danger of German competition is overrated. Many expressions against the proposed tariff were in evidence at convention. European imports needed to start trading.

**T**HE chief interest to the automotive industry in the annual convention of the American Manufacturers Export Association, held in New York City during the first week in October, was the universally expressed conviction that foreign trade, although it totals no more than 10 to 20 per cent of our total business, is essential to the return of prosperity to the United States. With this belief was coupled a general feeling that our overseas business has passed its lowest point and that a trade revival may be confidently expected in the coming months. The recovery, of course, will not be sudden and it will not come as a boom, but, nevertheless, better conditions in this part of our business are on the way.

The association is a general one and numbers among its thousand members manufacturers of all classes of goods suitable for the export trade. Among these are automobiles, trucks, equipment and other products of the automotive industry, many firms of which are members of the association. Consequently, the gathering brought together a number of export representatives from the industry, although, unfortunately, no part of the program specifically considered the automobile and its place in our foreign trade. However, the association recognized the growing foreign position of the industry by electing J. Walter Drake of the Hupp company, chairman of the Foreign Trade Committee of the N. A. C. C., as a director.

Delegates and speakers at the convention were chiefly concerned with three things. These were international credits and financing, which included the exchange situation; the proposed American tariff changes, and the better tone prevailing and predicted for our overseas trade. As to the first, it was generally agreed that events would have to take their course and that the correction or stabilization of exchange depended upon many factors. Par value for many foreign currencies cannot be expected for many years, and, in the words of more than one speaker, the present monetary units of some may fall by the wayside to be replaced by other standards. Stabilization, through mutual and co-operative efforts by the great banks of issue of the United States, England, France, Italy, Holland and Spain, was given as a possibility by Secretary Hoover, who addressed the annual dinner, and it was hoped by him that some method might be worked out which would do away with the recent violent week by week fluctuations that have been so characteristic of certain divisions of the exchange market.

The proposed tariff was not popular with the members of the association. No more so was the American valuation plan. Only one speaker favored the changes

that Congress has proposed and he was greatly outnumbered by others throughout the meeting. The position was made clear by James M. Anderson, Jr., of the Chase National Bank of New York, in considering the possibility of the dumping of low-priced goods from Europe or other sections. He said:

"Many American manufacturers are apprehensive of European competition, notably from Germany, and they are urging that high tariff barriers be erected to prevent the influx of foreign goods. During the first eight months of 1921 Germany sent us \$52,000,000 worth of goods and took from us \$263,000,000. There is nothing in these figures to suggest a very imminent danger. But the most welcome thing that could come about, the thing that would promise for a real revival, would be a real and vigorous increase in imports to the United States of European manufactures. It would start the circle of trade going again."

This position was recognized even by Senator Walter E. Edge, the New Jersey representative in the Senate, who is best known for the bill bearing his name that authorized the formation of foreign trade financing banks. Senator Edge stated that he favored protection, but that Europe must send goods to the United States in order to restore her financial and industrial status. He proposed that the tariff act give broad discretionary powers to the President to control various schedules. The President, with the possible assistance of the Secretary of the Treasury and the Secretary of Commerce, would be authorized to regulate the rates to protect any American industry threatened by low-priced, foreign-made goods.

## Hoover Predicts Price Stabilization

Secretary Hoover declared that European competition of low-priced products could not be continued long. The same economic factors were at work throughout the world, he said in substance, and that would bring about a condition of more stabilized prices. He was distinctly against any belief that Germany has achieved a solid foundation in her present show of feverish prosperity and believed that the continued inflation of the mark will ultimately cause a sharp turn in the minds of those who fear German competition.

This competition was also a subject that engrossed the delegates, many of whom were at a loss to know just how strong a position Germany had obtained in her former foreign markets. Unfortunately, few direct references to this were made by the speakers. The attendants, however, were unusually frank in declaring that German competition had been greatly overrated in the general markets and that American manufacturers

could compete on price to-day in a majority of the world markets.

George Weston, general manager for South America of the American Express Company, made this an important point in his talk at the luncheon on the opening day. With specific reference to textiles, he related an experience during August with three textile salesmen from the United States in his office at Buenos Aires. These men, he said, were confident that they could compete on price, service and delivery with their lines, provided Argentine exchange went no lower than it was at that time. Weston then showed that the Argentine currency had appreciated materially since the conversation referred to and, consequently, orders for textiles, hardware and other lines were again being booked.

### The South American Market

Weston was one of the few speakers whose talks carried an intimate and recent knowledge of particular foreign markets. He has just completed a ten months' visit to Brazil, Uruguay, Argentina and Chile, and has unbounding confidence in their fundamental strength. In Brazil, he said, the shelves of interior stores are almost bare of all goods, and, as a result, inquiries are coming to the larger centers that will result shortly in new business and further liquidation of whatever stocks are held in the customs houses. Brazilian merchants have been hard pressed, although an improved condition is already apparent, and he counseled that all credit risks to that country should be carefully scanned.

Argentina and Uruguay were looked upon by the speaker as offering more immediate business. With general betterment expected by their bankers and business men, Weston said that he would not be surprised to see our trade improve rapidly with those two countries. The last year crops in Argentina have now been sold and anxiety as to the wheat production for 1921 has been allayed by recent rains. Chile was pointed out as presenting a condition similar to Brazil. The demand for nitrate had dropped almost to nothing, but there now are "evidences that this nitrate stagnation cannot con-

tinue much longer and Chile will again come into her own."

Another important subject covered by Weston was that of credit allowances.

"The day of cash against documents at New York has passed," he said. "Fortunately the Germans have not reverted to their old methods of extending credits for periods of six months, a year or two years, but all of the Europeans are quoting 60-, 90- and 120-day terms. We must meet these allowances if we are to do business.

"On prices we are to-day doing business in many lines and new orders are being placed. The quality of goods from Europe is generally lower than from this country and this is being recognized. The only things I have to deplore in regard to our foreign trade are the lack of perseverance and the lack of knowledge as to South American needs of many of our manufacturers."

The picture of Europe, as given by several speakers, was both bright and dark. The latter was almost entirely one of finance, whereas it was conclusively shown that great strides had been made since the armistice in restoring the economic and social structure of a majority of the continental countries. Secretary Hoover was one who has been greatly impressed by the forward movement of Europe in this regard. Another was John S. Lawrence of Lawrence & Co., Boston, who summed up the European situation by saying that the continent had made a steady improvement in industry and agriculture but had steadily declined on the financial situation.

This brought up the reparation payments by Germany, which was a recurring subject for discussion. Several speakers recognized that the United States should have some part in the reparations deliberations. W. F. H. Koelsch of the New Netherland Bank of New York, whose paper was read, expressed the possibility that the allied leaders in Europe might propose some change in the payment system instead of having such a request come from Germany.

Myron W. Robinson of the Crex Carpet Co., New York, was elected president of the association to succeed William C. Redfield, former Secretary of Commerce.

## New Theory of the Slotted Wing

IN a paper recently read before the Society for Aeronautical Science at Munich, Dr. Betz dealt with a certain development in sustaining planes or aircraft wings due to Lachmann in Germany and Handley Page in England. The object is to increase the lift by providing slots in the wing parallel to the leading edge. If these are to be effective they must extend without interruption across the entire width of the wing. This arrangement may also be regarded as an extra plane of small depth placed in front of the main wing at its leading edge so that there is only a very small space left between the two. The maximum lift of the plane is thereby increased by 80 per cent or more. There are different explanations of this phenomenon. One is that the small plane located in front of the main plane is located in an air stream whose conditions of flow are determined by the main wing. It follows that at the leading edge of the main wing the air speed materially exceeds the speed of flying. The reactions of the air on the small wing in front therefore are considerably greater than if it passed through space at the flying speed.

The new explanation of Dr. Betz is based on the fact that for a given speed the lift of a plane increases with the angle of incidence until the air stream on the upper

surface can no longer follow that surface. If the angle of incidence becomes too big, a new condition of flow develops, the air stream separating from the plane, creating a field of eddies which grows with the angle of incidence. Such eddies have a tendency to form even in the case of small angles of incidence, but the air, passing over the plane, immediately washes them away, and thus maintains a smooth, lift-creating stream. In the case of large angles of incidence this becomes impossible. But if the air stream on top of the plane is reinforced by air passing through the slot in the wing from the under to the upper side, the lift-creating flow conditions can be maintained even with larger angles of incidence. New energy is being supplied to the air stream on top of the plane by the air flowing through the slot, which enables it to continue to wash away the eddies. This energy has to be paid for, however, the phenomenon being accompanied by increased drift of the slotted plane as compared with a plane without slot.

This new explanation is valuable for the reason that it furnishes a basis for judging the value of new plane combinations of the kind referred to, and facilitates the arrangement of systematic test series in a field where the number of possible combinations is almost without limit.

# The Purpose of the Labor Articles in AUTOMOTIVE INDUSTRIES

Mr. Tipper, in this article, points out the necessity for studying the human side of production activities with a view to preventing trouble rather than waiting for difficulties to arise and then attempting to find a remedy. Production cost depends largely upon human organization.

By Harry Tipper

SOME of the subscribers of AUTOMOTIVE INDUSTRIES who favor me with their constructive criticism of these articles, have asked me of late why the continuing of the labor articles, now that the labor problem has passed. This is a reply to those questions, mainly for the purpose of clarifying the problem which faces industry and showing the imperative necessity for studying the human side of the case, at least as carefully as we are studying the mechanics.

The labor disturbances which were so violent in 1919 and the early part of 1920 have subsided to a very large extent. Strikes are no longer occurring with the same frequency. Grievances are being adjusted where there was no basis of adjustment previously. These things are true sufficiently to remove the problem of human efficiency from among the visible problems before the manufacturer. The manufacturer is now more concerned with the production costs because of the declining prices he is obliged to face.

It is important that the significance of this situation be thoroughly understood. Prices have declined materially from last year and these new prices have been arranged largely for the purpose of meeting market conditions and are not particularly related to the costs of production. The authoritative economists are almost a unit in declaring that for a number of years there will be a general tendency for prices to decline over the surface of industry, although this will not apply to all industry to the same degree, nor will it be true without intervals of increasing prices from time to time.

## Necessity for Lower Costs

However, the best information on the economic situation indicates a necessity for lower costs. These lower costs must come out of the production of the product, or the commercial branches and marketing necessities of the same product. It is probable that the increased efficiency will have to be secured from all departments of the business, that production methods must be improved, and production costs reduced per unit of goods, and also marketing methods be improved and marketing costs be reduced per unit of sale. The mechanical fabric of industry is too great and too complete in its character and subdivision to be improved very rapidly in itself.

It is worthy of note that in all reports of the Waste Committee of the American Engineering Council, the large percentage of the waste is due to human inefficiency, the costs of human neglect and the results of human failure.

In every industry in the country these costs represent a larger total than the lack of balance in the mechanical fabric and the possibilities of immediate improvement in the character of the mechanical equipment.

Events have shown that it is not possible to figure on a certain efficiency of labor on the average, as the efficiency fluctuates with the conditions of employment and the character of industrial development. The problem, therefore, is one of harnessing a larger part of the potential capacity of the individual human being to active and continuous service in the production of commodities.

William James pointed out a good many years ago that only from 40 to 60 per cent of the intellectual capacity of the average individual was put to work. The only failure of that estimate is that it is too high. The potential capacity of the average intellect for judgment, accuracy and order is very much greater than the expressed skill of the same intellect and the expressed skill is the only part that can be applied to the job.

This problem of harnessing a larger part of the average capacity of the man to the job is not a theoretical one. It does not bear any relation to those academic researches which are concerned with the general development over periods of generations and do not appeal to the business man, who is immersed in the development of product for the immediate future and for his own generation only.

## Individual Efficiency Helps

The organization which is able to increase the individual efficiency to a fair degree is in a better position to withstand the stress of competition than that organization which has neglected the human side of the question. The severity of competition is increasing, because the manufacturing capacity is larger than the absolute requirements and this competitive intensity will demand an analysis of cost very much keener and more accurate than our previous analyses. It will require a much closer study of the factors that enter into the costs, and how these factors can be influenced. Labor disturbances may have ceased to operate as a visible problem for the time being, but the problem of putting the human potential capacity to work is so far from solution and so necessary a matter of study, that it must be considered with the same care now given to the mechanics of production and the elements of salesmanship.

These articles have missed their purpose and shot very wide of the mark if they have failed to indicate that the question of strikes or group disturbances is only

one symptom of the problem and not the reason for considering it.

No engineer worthy of the name would defer his study of mechanics of production until the machinery of the factory broke down, and then begin a hurried attempt to find some way to make it work again. Every item of this mechanical production is analyzed sufficiently to enable the manufacturer to depend upon keeping his plant going with fair regularity, with little lost motion and with a fair dependability of result.

The same manufacturer does not consider the human problem until the system breaks down and the men refuse to work. In fact, many manufacturers are inclined to wonder why the problem should be discussed so long as the machinery of human group organization does not entirely break down and leave them stranded.

Behind the present engineering skill and expressed efficiency there are a hundred years of development in the practice of mechanical equipment and the study and improvement of machinery.

The bibliography of works on production from the mechanical side runs into thousands of books and presents a wealth of detailed consideration from which the student can learn the past experience in all kinds of manufacture.

No such background is to be found in the case of the human being in industry. Books on organization have not dealt with human organization, but with systems of controlling human organization. Books upon management have dealt very rarely with the development of men, but very frequently have enlarged upon the systems of centralized instruction and control by which men can be made to do as they are told.

All through this history of production there is an absence of consideration for the human factors in production, which is as illuminating as it is disturbing.

With so little background for study, it is difficult for the average man to conduct researches into the subject. Most men in their study have been accustomed to have their subject separated from the rest of the fabric of industry, carefully analyzed, and dished up, so that they would not have to search through innumerable volumes to find it out.

It is not possible to do this in connection with human matters. Books which would suggest factors of importance in human growth are classed under many subjects in the libraries and called by many names by the publishers. It is necessary to read a number of books in order to get one clear suggestion. Consequently, the average man, who is busy with the operations of the plant, finds it impossible to carry his studies of this subject very far. He cannot spend the time in reading books which are so far away from his practical operations in order to find a suggestion that he may use. His mind is occupied by his practical responsibilities, so that the suggestions would pass unnoticed most of the time, because they have not been applied to his particular case.

It is important, therefore, that the student who has been able to conduct such analysis and research should present his conclusions, refer to his authorities, consider the practical experiments, and draw the principles and fundamentals from his wide consideration and experience with the needs of the busy man in mind. This service should be performed continually, because only by that means can the subject be opened up and applied to the manufacturing necessities.

The big problem before the manufacturer to-day is how to reduce costs. The production costs must be reduced along with the other costs. How to reduce these costs and to retain the efficiency or to increase it, are the important elements of the problem. The problem cannot be solved by merely reducing the activities. It may be solved by increasing the activities through the reduction in the cost of the individual unit, and this means an increase in the efficiency of work upon each unit.

Because so much of the waste is the waste of human capacity, the problem of production costs is very largely a problem of human organization, and this is developed from an understanding of human necessities.

This is not a job to be done by a half hour's discussion or a little ginger talk. It must be studied and experimented with carefully and continually. Hence, these articles and their continuance when there is no visible labor disturbance and there appears to be no particular difficulty on the horizon in connection with the skilled or unskilled labor portions of the human organization within the factory.

## Unemployment in Great Britain

**T**HOUGH there is much dispute—and with fair reason—concerning the English Government's periodically issued figures as to the cost of living in Great Britain, there is no challenge to the data concerning wage revision and number of unemployed. In August, 3,160,000 persons had a revision of wages; of which 3,070,000 suffered a reduction and nearly 90,000 received an increase. The gross reduction on full time wages was about \$3,500,000, made up of rates ranging from 2 cents per hour (47-hour week) for most trades, up to 72 cents per week for day-rate metal trades workers and 7½ per cent for metal trade piece workers.

Unemployment among the trade unions fell from 16.7 per cent at the end of July to 16.5 per cent in August, the total of unemployed registered at the labor exchanges on August 26 being approximately 1,573,000 persons, of whom 1,190,000 were men. A bad feature about the unemployment figures is that a vast number of persons have exhausted the period during which they were entitled to

State aid. They have now to qualify for a further period by being out of work a number of weeks. Meanwhile they have to be supported and, at present high cost of living, obviously the task is unusually difficult. Terms offered by the Government for municipal aid in road making and improvements have been rejected by local authorities as demanding too high a rate of interest.

It may be noted that in the automobile works labor of the skilled sort (fitters and turners) in Britain is averaging 45 cents per hour for 47-hour week, but Ford workers receive a uniform rate of 52 cents per hour besides a yearly bonus plan.

**A** BOOK containing petroleum laws governing leases, concessions and explorations in all the countries of North, South and Central America has been compiled by the Bureau of Mines in Washington. Included in the collection is the leasing act enacted by Congress and the petroleum laws of the various states in this country.

## Headlamp Lenses with Key Slots

THE majority of the special lenses used on headlights with the object of reducing the glare act on the principle of the prism, the rays of light being turned downward by refraction in passing through the lens. In order that such lenses may perform their function efficiently they must be held in the lamp shell in a definite position; if they should turn around their axis to any appreciable extent they may fail to accomplish their purpose and even be a positive detriment.

So far the friction between the lens and the lamp shell has been depended on to keep the lens in the position in which it is placed when fitted. It has been proved by experience, however, that this method of holding is not reliable, especially in the case of lamps on the cheaper grades of car, which lamps are generally made of very light stock. In the course of operation the lens will shake loose and is then very apt to turn around. As this is a matter which does not materially affect the operation of the car, and as the driver feels that he is complying with

the law if he has his lamps fitted with one of the types of approved headlamp devices, it is likely to be neglected, and hence the intent of the law with respect to glare elimination is defeated.

The remedy for this difficulty is obvious. All that is necessary is to provide the lens with one or more keys or key slots and the lamp shell with corresponding members. The matter has been taken up by the Standards Committee of the S. A. E. Once the locking means has been standardized, the lens makers can go ahead and change their molds with the assurance that lenses from these molds will fit any lamp of the corresponding size, and this particular difficulty will be eliminated.

## Building Foreign Confidence

DESPITE scientific theories as regards salesmanship, personal contact plays an important part in modern business. Advertising has a definite function in the selling scheme, but it must be backed up by personal visits by salesmen. These personal contacts do more than get business; they make possible the establishment of close business friendships and make it easier to build up mutual confidence between buyer and seller. Such confidence means an actual reduction in selling costs.

In merchandising automotive products to foreign countries, however, this personal contact is usually difficult and often impossible to get. Consequently, the building up of confidence is a more difficult matter than in domestic business. Sharp practices in domestic business will finally ruin any confidence that may be built up, but the personal contact that is possible will usually prevent misunderstandings.

In the case of foreign business, however, even the appearance of evil is especially to be avoided. It takes letters a long time to reach their destination, and it takes a long time to overcome an unfavorable impression that may arise through misunderstanding. Putting aside national pride for the moment, it is undoubtedly true that the handling of our foreign automotive business in the past has not always been such as to tend toward building up confidence in American methods.

An instance is related in which a representative of an American car manufacturer in China told a Chinese merchant that in order to be sure of getting 10 cars a month he should contract for 100 a month. The transaction took place during peak production times, and the salesman told the Chinese merchant that his American factory was so hard pushed to supply cars that it supplied only about 10 per cent of every order which they got. The Chinese merchant took the word of the salesman concerning this practice and ordered accordingly. He received no cars at all for some eight months. Then the slump in the American market came. The Chinese merchant then received a shipload of 600 cars in one lot. Naturally he was unable to pay for them and could not sell them. As a result these cars are probably on some Chinese dock at the present time.

While such practices are not, of course, common among automotive exporters, the example cited is a

striking, though exaggerated, illustration of how the confidence of foreign buyers may be broken down. This one experience probably created a prejudice against American methods among all the Chinese merchants with whom this particular merchant has since come in contact. For, just as we are likely to judge the practice of an entire country by the actions of the individuals with whom we have dealt, so the foreigner is likely to judge American standards of practice in the same way. The justice of such judgment may be questioned, but the fact remains.

In handling foreign business extreme care is necessary, even in small matters, to make certain that there is no opportunity for misinterpretation or misunderstanding. Practices understood at home may not be understood abroad.

## Motor Buses in America

ANY intelligent analysis of the transportation system in this country must recognize the importance of the motor bus as an important potential factor in solving the problems presented. The development of both city and interurban bus lines in England strikingly illustrates the scope of the motor bus in an economically sound solution of transportation problems.

There are even greater possibilities for a similar development in this country, so that the motor bus field is a potential market worth the attention of truck manufacturers. In considering this market, however, many variable factors confuse the situation at present. On the commercial side, it is not yet clear what agencies will be the most important in developing bus transportation and consequently in buying buses.

The existing transportation interests may realize possibilities of the bus as an ally. They may install and operate bus lines in connection with their present services, strengthening and substituting as the transportation economics of the individual situation dictate. It was largely along these lines that the English development took place, and there is some evidence of similar action in this country. On the other hand, the spirit of opposition to buses may prevail among existing transportation agencies, in which case bus development may be through municipalities or independent bus line operators.

Sufficient progress has not yet been made to determine what lines the major development will take in the United States. The potential market for buses is undoubtedly present; the concrete market must be studied very carefully.

But motor bus development will depend largely upon engineering as well as commercial developments. Many engineers who have studied the problem carefully are of the opinion that the standard truck chassis is not suitable for motor bus work. The ability of the engineers to modify or redesign the truck chassis for bus service and the willingness of the truck manufacturers to make this special design are large factors in the future of bus development.

Every truck chassis which fails to perform effi-

ciently and economically when used as a bus adds just so much resistance to the rapid development of a potentially profitable market. Every chassis which enables the operator to make a profit and the passenger to ride in comfort at a reasonable price hastens the development.

While it is not always possible to adjust immediate efforts exactly in line with permanent development, the various factors mentioned should be seriously considered in marketing efforts of this kind.

## Tractor Dynamometer Trials

FOR some years the question has been discussed in tractor circles whether scientific tests in connection with tractor demonstrations would not prove of help to the industry. It was realized some time ago that the mere demonstration had practically played out as an attraction to the farming community, and if the tractor industry was to be further promoted by field demonstrations, accurate measurements of drawbar pull, drawbar horsepower and fuel consumption must be made, so that data could be put into the records which would bear weight with prospective purchasers.

During the past year excellent data concerning American tractors have been furnished by the official tests of the University of Nebraska. As it is impossible for a tractor manufacturer to sell his machines in Nebraska without first submitting them to these tests, practically all tractors now manufactured in this country have been tested at Lincoln, and as the results are available to the general public the need for such tests at tractor demonstrations has been eliminated. It is more than likely, however, that if dependable tests had been carried out at the national demonstrations some years ago the Nebraska tractor law would never have been adopted.

In England the need for serious scientific tests in connection with public trials has also been felt, and at the trials recently held at Shrawardine every tractor was given a six-hour test with a traction dynamometer. An endeavor was made to obtain data bearing on the relation between the maximum obtainable drawbar pull and the weight on the drivers. This is a very important factor in tractor design, because the drawbar pull is one of the factors which measure the working capacity of the tractor and if a given drawbar pull can be obtained with less weight, the over all efficiency of the tractor can be increased. It is readily realized, however, that the ratio referred to depends not only upon the nature but also upon the condition of the soil. Its value is naturally smaller when the soil is wet than when it is dry. It so happened that during the Shrawardine trials the soil was quite dry, yet the drawbar pull of thirty-six out of thirty-eight machines was limited by the adherence of their drivers and that of two only by the engine power. It might have been expected that if any type of tractor would stall its engine under excessive loads, it would be the chain-track type, because of the admitted better adherence of this type, but as a matter of fact the two tractors that stalled their engines were of the wheeled type.

# N. A. C. C. Discusses Dealer Problems

## Car Makers Urged to Give More Help

### Used Cars, Financing and Contracts, Subjects Considered at Their Annual Meeting

NEW YORK, Oct. 10—One of the greatest problems confronting the automotive industry is found in the relation between manufacturers and dealers. This fact was recognized at the annual members' meeting of the National Automobile Chamber of Commerce here last week when practically the entire session was devoted to consideration of various phases of the subject.

#### Difficulties Not Minimized

The convention was attended by more than 100 factory executives who made no attempt to minimize the difficulties involved in finding a market for used cars, financing dealers and meeting dealer requests for contract changes.

The great volume of used cars on the market was held to present the most difficult obstacle to continued sales of new cars in large volume. The most concrete proposal in this connection was that manufacturers should study not only the market for new cars but for used cars and govern their production accordingly. It was apparent, however, that no concerted action can be expected along this line and that it will be up to each individual company. Some of them seemed to feel that there was plenty of demand for their output, but that some of the other fellows should limit theirs.

#### Some Companies Assisting

In fact, as the discussion continued, it became clear that no uniformity of action in relation to any of the big problems of the industry is likely at this juncture. Each manufacturer will study his own resources and his own needs and act accordingly for the benefit of his dealers. Those who can help them to help themselves probably will do so, but it was the view of the majority that the manufacturers have troubles of their own and that they should not be expected to assume the burdens of their dealers. They held that in the dealer end of the industry there should be a survival of the fittest and that those who are not good business men or who have scant financial resources of their own should be eliminated as rapidly as possible.

It was brought out that several companies have been assisting their dealers by helping distributors carry stocks or handle dealer paper. This disclosed what

appears to be a steadily increasing sentiment in favor of eliminating distributors if they are not strong enough to finance themselves in favor of a system where all dealers will work under the direction of factory branches or regional factory warehouses.

There was a feeling that companies which are in a strong enough position to do so should assist dealers in paying the carrying charges of some reputable financing company to handle vehicles actually on their floors.

The manufacturers were willing to assist in every way in their power in selling bankers throughout the country on the essentiality of the motor car and thereby inducing them to assume a more liberal attitude in regard to dealer paper. It was felt that the recognition given the industry by the big bankers of New York and other large cities would have a beneficial effect.

Financing of dealers was considered even more intensively by the truck manufacturers than by those in the passenger car field. They listened to addresses on this subject by J. H. Shale, vice-president of the Bankers Commercial Security Corp., and John J. Schumann, Jr., vice-president of the General Motors Acceptance Corp. Both spoke along the same general lines.

(Continued on page 747)

## Carter Motors Formed with \$2,000,000 Capital

WASHINGTON, Oct. 10—Incorporation of the Carter Motor Car Co. with a capitalization of \$2,000,000 has been announced here. The company was incorporated under the laws of South Dakota by L. L. Stephens, Frank L. Carter and A. Gary Carter. Buildings formerly occupied by the Washington Motor Car Co., at Hyattsville, Md., a suburb of Washington, have been taken over for a factory.

The advance notices issued by the incorporators state that a small car will be marketed at an attractive price. The company says the car will be equipped with easy-riding comfort springs, the patent for which is controlled by the incorporators.

#### DENIES KISSEL APPEAL

WASHINGTON, Oct. 10—The Supreme Court of the United States to-day denied the Kissel Motor Car Co.'s appeal for a hearing in a case which involves the construction of the Texas restraint of trade law. The Kissel company, whose plant is located at Hartford, Wis., gave an exclusive territorial agency contract to an agent who became indebted to the corporation. The lower court held that the company could not recover because its contract violated the Texas law.

## Willys Progresses in Reorganization

### Completion of Negotiations Calling for \$25,000,000 Loan Expected in Few Months

NEW YORK, Oct. 11—Satisfactory progress is being made in the plans for the reorganization of the Willys-Overland Co. They now have reached a point where it is expected negotiations will be completed in a few months. A letter soon will be sent to stockholders of the company asking for their proxies.

The plan has been worked out by a committee of bank creditors headed by Ralph Van Vechten, vice-president of the Continental & Commercial Bank of Chicago. It calls for a loan of \$25,000,000 in the form of a bond or note issue which will run 10 years or longer. It has been understood that Kuhn, Loeb & Co. would underwrite this issue.

Bank loans of \$10,000,000 will mature Nov. 1, and it is understood the company will ask for an extension of four months. The bank debt will be reduced 10 per cent by the payment of \$1,800,000 in cash on Nov. 1. Another reduction of 10 per cent was made by the payment of \$2,000,000 in cash on Aug. 1. The bank creditors are ready to agree to the extension and it is expected that the reorganization plans will have been matured and that the \$25,000,000 will be available before the expiration of the four months.

Willys-Overland has no bonded indebtedness and it can place no mortgages on any of its properties without the consent of two-thirds of its preferred stockholders.

## Electric Auto Lite Secures Durant Work

TOLEDO, Oct. 10—A contract for a supply of ignition, starting and lighting equipment for its new four and six cylinder motor cars was closed by Durant Motors, Inc., with the Electric Auto Lite Corp. here, it was announced to-day. T. W. Warner, vice-president of Durant Motors, Inc., and president and general manager of Durant Motors of Indiana, Muncie, negotiated the contract with C. O. Miniger, president of the Auto Lite Corp., on Saturday.

The contract will mean a rapid return to normal production at the Auto Lite plant here.

"Already business has taken a remarkable turn for the better with us," declared President Miniger. "We have increased our force by 200 employees in the last few days. Our program for October is 10 per cent larger than September and in November will increase."

# Seager Patents Are Upheld by Court

## Essentials Retained in Webb Jay System

### Infringement Charges Against Stewart-Warner Sustained in Far-Reaching Decision

CHICAGO, Oct. 10—In an opinion handed down in the Federal Court here, Judge George A. Carpenter holds that the Seager patents on vacuum-tank equipment are valid and have been infringed by the Stewart-Warner Speedometer Corp., which was made defendant in the action. The plaintiffs were James B. Seager, Arthur L. Payton and Cornelia F. Thomas.

#### Litigation Long Pending

The opinion is the outcome of patent litigation which has been pending for some years and which came to trial last June.

While Seager's patent relates to the application of the vacuum feed to stationary engines operating without a throttle valve, another patent issued to Harrington, also in suit, extends the system to throttle controlled engines, and the court regards the claims as sufficiently broad to cover the application of the vacuum principle to all types of engine.

In referring to the defendant's system, the court decides that while the Webb Jay invention is doubtless an improvement on anything either Seager or Harrington described, the essentials of the Seager combination are retained in it. In this connection the opinion says:

#### Applicable to Automobiles

"Webb Jay, the inventor of defendant's so-called infringing system, realized that in climbing a steep hill with an automobile the suction of the engine will be inadequate to develop in the reservoir sufficient suction to elevate fuel from the low level storage tank. Jay realized the desired results by enlarging and deepening the lower compartment of his reservoir.

"This made it possible for the level in that compartment to vary as much as six or seven inches. In order to make this reserve capacity available for supplying the carbureter, it was necessary to locate the entire reservoir at a level above that of the carbureter nozzle.

"It was undoubtedly an improvement on anything Seager or Harrington had done, for the defendant to enlarge the reserve capacity of the lower compartment of the reservoir, but this enlargement, and the inclusion of a float chamber and valve in the discharge conduit leading to the carbureter nozzle, does not organically change or avoid the construction, mode of operation and result of the Seager and Harrington inventions.

"The essentials of the Seager combination

are retained in defendant's equipment, notwithstanding that there have been added, first, the Harrington improvement of a two compartment reservoir with intervening valve, and, second, the automatic suction intermitting mechanism."

The court states that while the Seager invention has never been sold to the automobile trade, which was one of the contentions of the defendant, its adaptability for use on motor cars as well as on stationary engines has been demonstrated. Continuing its opinion, the court says:

"In the defendant's system it is the presence of the Harrington invention which permits the use of an obstruction (a throttle) in the airline to the engine at a point between the carbureter nozzle and the point at which the suction conduit is tapped in, so that the suction of the engine, however high it may go, may still be utilized to develop a correspondingly high suction in the upper compartment of the reservoir for elevating fuel into it, while the lower compartment, which is always under atmospheric pressure, will continue to feed fuel to the carbureter, no matter how relatively low the suction upon the nozzle may become; and this, notwithstanding that in the defendant's system there is added to Harrington the automatic suction intermitting mechanism, and notwithstanding that the substantial constancy of the level of the supply to the carbureter nozzle is effected by the float chamber and valve rather than by the overflow pipe of Harrington.

(Continued on page 750)

## Brush Charges Ansted Motor Is Infringement

DETROIT, Oct. 10—Alanson P. Brush of this city has brought through Williams, Bradbury, McCaleb & Pierce, attorneys who have recently been engaged in the Seager and Harrington patent suit against the Stewart-Warner company of Chicago, a patent infringement suit against the Chicago sales organization of the Lexington Motor Car Co.

Brush alleges that the Ansted engine used in Lexington cars infringes a number of his patents. He asks that the defendant be made to account for past use and sale, and be restrained from further use and sale of cars equipped with these engines. The Ansted engine has been used in the newer model Lexington cars and has recently been adopted by Durant for his six-cylinder car.

#### INSTITUTE CHANGES PLANS

NEW YORK, Oct. 11—After careful consideration the board of directors of the American Petroleum Institute has decided to hold the second annual meeting at the Congress Hotel in Chicago, Dec. 6, 7 and 8. Tentative plans to hold the meeting in Kansas City have been cancelled. The program will be announced in the near future.

## Tire Manufacturers Increasing Output

### All Akron Companies Report Improvement in Sales for Past Month

AKRON, Oct. 11—There has been no appreciable slowing up of the rubber tire industry this fall, despite the fact that the tire manufacturing business customarily enters a period of less activity either in September or October, and does not emerge from it until January or February of the succeeding year.

Instead of curtailing production, Akron rubber companies are increasing their output and expect to make further increases between now and the first of the year. History shows that a 15 to 20 per cent decline in September sales as compared to August sales can be expected in the tire industry each fall; but this year conditions are reversed. Practically all companies here reported increased sales for September and are planning further increases during October.

#### Goodrich Inventory Reduced

The B. F. Goodrich company, prepared for an anticipated normal sales decline in September over August, reports September sales far in excess of those of August. The company also has gone on a basis of 200,000 tires for October and plans to increase production steadily for the next three months. Goodrich has reduced its finished goods inventory by nearly a million tire units since the first of the year and is now down to an inventory of 300,000 tires. This is actually a smaller number of tires than the company heretofore has had to keep en-transit. The low inventory, Goodrich officials say, reflects the improvement of the past few months in transportation conditions. Goodrich now is at the point where an expansion of inventory is possible.

#### Firestone Leads

Firestone continues to lead in tire production, with a daily ticket calling for 22,000 tires. Firestone was the only major rubber company to climb back to its 1920 peak production, having returned to a production of 28,000 tires daily three months ago. Goodyear continues on a basis of 16,000 tires daily.

Firestone, Goodyear, Miller and the General Rubber Co. report that both in units and sales volume their 1921 business will exceed that of 1920. This is considered extraordinary in view of the peak business done by all rubber companies during the first six months of last year and the long duration of the tire industry slump.

## Urging Surrender of Army Equipment

### Highway Officials Appeal to Harding for Transfer to State Road Commissioners

WASHINGTON, Oct. 10—President Harding has received an appeal from the executive committee of the National Association of State Highway Officials to compel the War Department to surrender to the highway commissioners of the various States all available surplus motor equipment and other road building machinery. They are also trying to force quick action on the part of Congress in disposing of the highway legislation. The recommendations of the unemployment conference for the extension of road-building have been seized upon by this committee in an effort to impress both the legislative and executive branches of the Government as to the needs of material and Federal funds.

#### Wreckers Wish Material

Negotiations are under way looking forward to an adjustment of differences between the War Department and the Bureau of Public Roads, regarding the disposition of motor vehicles and supplies now in the possession of the former. It is understood that the department is daily beset with demands from junk dealers and so-called wrecking corporations to be permitted to take over the motor vehicle surplus stocks, practically at prices dictated by the dealers themselves. These men have received no encouragement under the present administration of the department. One of these concerns is said to have very powerful political backing, and has been insistent in its demands, but whether the influences in its behalf are operating to prevent action on pending bills authorizing the transfer of road building machinery to the State highway commissions has not been disclosed.

One section of the pending bill not only authorizes but directs the Secretary of War to transfer to the Secretary of Agriculture, upon his request, "all war material, equipment and supplies now or hereafter declared surplus from stock now on hand and not needed for the purposes of the War Department, but suitable for use in the improvement of highways," the Secretary of Agriculture to distribute such equipment among the highway departments of the several States.

#### Will Relieve Unemployment

In the pending good roads bill, which is in conference, an appropriation of \$25,000,000 is provided, to be available immediately, and an additional \$50,000,000, six months after the passage of the act. As reported to the Senate, it carried \$100,000,000 for the present fiscal year and a like amount for the fiscal year 1923, but demands for economy and reduced public expenditures forced a

compromise at \$75,000,000, which if agreed to in conference, will make a grand total of \$369,000,000 provided within the last five years as Federal aid in the construction of good roads throughout the country.

The highway commissioners insist that the States could not buy sufficient machinery for manufacturers at this time to undertake an extensive road-building program. However, they contend that with the transfer from the War Department it would be possible to build hundreds of miles of road, thereby giving employment to thousands.

The House will soon take up the bill and it is said that commissioners are canvassing the various State delegations in order to bring pressure to bear at the right moment.

### Seek Approval of Plan for Closing Cotta Plant

ROCKFORD, ILL., Oct. 8—Although receivers of the Cotta Transmission Co. have operated the plant in the last few months to show a net profit of \$5,139.14, the referee in bankruptcy will be asked to approve the recommendation of the creditors that the plant be closed and bids asked for the remaining assets. The factory, under the court order, will operate until sanction is given the closing plan.

Receivers' statements show orders on hand Sept. 17 amounting to \$2,308.50, with liabilities of \$250 and cash balance of \$45,162.20.

Alternative proposals made at a recent conference of the receivers and the creditors were operation of the plant pending disposal upon bids for its remaining assets or continued operation without a definite future program. Court approval would have been required, however, as the receivers' orders were to continue operation of the plant until the court ordered otherwise.

### Allen Receivers Ask Permission to Sell

COLUMBUS, Oct. 8—Creditors having consented and urged its liquidation, George A. Archer and William C. Willard, receivers for the Allen Motor Co. of Columbus, have applied to the U. S. court for permission to sell the assets at public auction. The assets consist of the plant, machinery and stocks. Claims against the company are in the neighborhood of \$2,000,000 and assets are estimated at something less than that amount.

#### AMERICAN ROLLS-ROYCE OPENS

SPRINGFIELD, Mass., Oct. 8.—After a close down of a few weeks the American works of Rolls-Royce are operating on a limited basis. S. deB. Keim, general sales manager, has just returned from an extensive trip through the West in relation to sales distribution and as a result a number of representatives have been appointed. From present indications, the works should be back in normal production at an early date.

## Space Is Assigned for National Shows

### Ninety-four Cars Will Be Exhibited in New York—Eighty-two in Chicago

NEW YORK, Oct. 6—More than 100 factory executives attended the annual members' meeting of the National Automobile Chamber of Commerce here today to draw space for the New York and Chicago shows. Greater interest even than was displayed last year was shown in the coming expositions.

All the applicants for space will be taken care of at the New York show, which will be held in the Grand Central Palace from Jan. 7 to 13, but the situation in relation to the Chicago show, which will be held at the Coliseum two weeks later, is not so satisfactory.

The overflow from the Coliseum will be taken care of so far as possible in the Armory at Chicago, but even these two buildings will not be adequate to meet the demand for space, and several companies will be unable to make displays.

Ninety-four cars will be shown in New York as compared with 87 last year, and 82 will be shown in Chicago. Only two foreign cars will be shown at New York. They are the Itala and the Vauxhall. The American cars which will be shown in New York but to which space has not yet been assigned are Hatfield, Bournonville, Essex, Rickenbacker and Kelsey. The Rickenbacker probably will be displayed at Chicago also.

The result of the drawing follows:

Note: In Chicago letter X after space means Coliseum or Annex; letter Y means Armory. In New York Show the A spaces are on first floor, B spaces on second, C on third and D on fourth. "Not" means "not showing" or "space not available."

\*Means "non-member of N. A. C. C."

New York Space	Car Name	Chicago Space
A-19	Buick	C-5-X
A-11	Dodge	D-1-X
A-15	Studebaker	B-2-X

(Continued on page 743)

## Employment Eases Used Car Situation

### Better Industrial Conditions in Indianapolis Promise Greater Business in New Sales

INDIANAPOLIS, Oct. 8.—The fact that unemployment here is on the decrease especially with the higher priced mechanics and salaried men is easing off the used car situation, according to dealers. Both lower and higher priced used cars are being sold now with greater ease than for some time. The situation is not what the dealers want yet by any means, but the present situation is indicative of what may be expected in case the industrial situation continues to improve.

For a time this summer the used car problem, especially in the high priced used cars, presented a real problem to dealers. Unless they were able to take in old cars it was virtually impossible to sell new cars to the prospects. The volume of new cars sold, while good, would have been much better had the dealers been able to move used cars. For a time much agitation was being stirred up to get a uniform system in taking in and disposing of used cars, especially with reference to the prices at which they were to be taken in. Most of the dealers in the city at one time had all the used cars they could handle and, because of the slowness of sales, they were unable to take in any more and thus make new sales. A relief in the sales of used cars will doubtless stimulate the sale of new cars, or at least the dealers here believe this will be the case, and it is on this supposition they are basing their assertions that October will be a good month.

The credit situation continues to improve. Local companies who finance buying of both old and new cars report that a noticeable improvement may be seen during the past thirty days and the dealers are finding money easier at the banks than for some time. There are many indications that interest rates will drop before the first of the year.

## 22,000 Studebakers Sold in Third Quarter

NEW YORK, Oct. 8.—Studebaker sales for the third quarter of the year approximated 22,000 cars, or nearly the number sold in the previous quarter. The output for the first nine months aggregated 55,000, which should bring the year's total to 70,000, a number in excess of the best previous year, 1916, when 65,885 cars were turned out. For weeks the company has been oversold on enclosed cars in spite of the fact that the Detroit factories are concentrating on these models.

Because of price reductions, profits of the second quarter, when nearly the full year's dividend of \$7 was returned for

the \$60,000,000 common, will probably not be maintained for the third quarter, the improvement, however, as compared with the third quarter of 1920 being at least 50 per cent.

October 1 Studebaker had more than \$9,000,000 cash in the banks, which is more than double its Jan. 1 balances, and since the first of the year has paid off, in addition, bank loans of \$3,500,000, preferred and common dividends for three quarters and has invested \$1,000,000 in securities.

## Durant Will Employ 4000 in Indiana Plant

INDIANAPOLIS, Oct. 8.—Thomas W. Warner, vice-president of Durant Motors of Indiana, which recently bought the Sheridan automobile factory of the General Motors Corp. at Muncie, has announced that eventually the Durant factory will employ 4000 persons in the manufacture of automobiles. The Durant company expects to have 800 men at work by Jan. 1. A large force of workmen is now employed in cleaning up the plant and setting machinery.

Plant No. 1 of the Muncie Products Co., a division of General Motors, has 75 more men employed than it had when it was running full time a year ago. Other plants of the Muncie Products Co. also are adding to their working forces weekly.

## Cork, Ireland, Votes Ford Freedom of City

CORK, IRELAND, Sept. 28 (*By Mail*)—Henry Ford has had the freedom of the city of Cork conferred upon him "as a token of the city's appreciation of his great interest in the industrial development of his native country," and the next time he visits Ireland he will be honored by a fitting reception headed by the Lord Mayor and the city officials. At the meeting of the city corporation when the honor was bestowed a letter was read from Henry Ford & Son pointing out that a lease of the park taken in 1918 bound them to lay out \$1,000,000 in buildings, and for a period of five years after the completion of the buildings to employ and keep employed at least 2000 men.

In spite of the most formidable difficulties they have erected buildings which covered over six acres of land at a cost of \$1,250,000, and have equipped them with the most modern machinery at an approximate cost of \$2,000,000. At the commencement of the work only about 10 per cent of the tractors was manufactured in Ireland; now 90 per cent is being made in this country, principally in Cork.

In addition they are manufacturing in the Cork factory complete engine and all cast-iron parts of the Ford car for the Manchester factory. There are 940 men employed and paid double the wages stipulated for in the lease. The expenditure on wages alone since the firm came to Cork has been \$2,125,000.

## Would Lessen Idle Through Road Work

### Association Offers Suggestions to Aid in Solving English Unemployment Problem

LONDON, Sept. 20 (*By Mail*)—In connection with the proposals for relieving unemployment by providing work for unemployed ex-service men in road construction, repairs and improvements, the Automobile Association has recommended to the Cabinet Committee on Unemployment that only such plans for highway work be adopted as will insure 90 per cent of the funds to be devoted to relief going in wages to the unskilled. In asserting that road making is primarily the work of an expert and the proportion of expenditure which can go into the pocket of the unskilled necessarily must be small, it urges that the money be spent on such work as can be done by manual rather than mechanical labor and that the employment must be found where the unemployed are at present situated; in other words, all over the country. It makes the following suggestions:

Appeals to be issued to land owners to give land adjacent to highways for the widening of bends and corners, the extension of visibility and the provision of footways.

The highway authorities acting with the Roads Department of the Ministry of Transport to schedule all offers, to set out the work and to decide the value of such work.

Assuming that one particular job is assessed at 100 days' work, that amount only would be paid and be divided among the number of men actually engaged. The rate per day would be variable according to the amount of work done.

The erection of wire fences and the planting of quick-set hedges or the re-erection of existing fences would be a matter of labor rather than material.

Such relief work would cover, in addition to the setting back of fences, felling and removal of trees, clearing of brushwood and removal of obscuring banks, better surface drainage, and eventually improved gradients and cross falls to the roads themselves when reconstructed or resurfaced.

Such work can be done remuneratively, it is held, in rural areas particularly. Waste can be avoided, the association says, when useful and necessary work only is undertaken on the basis that pay is by results rather than the actual time taken.

Relief of the unemployment situation along similar general lines has been suggested by automotive interests in the United States to the employment conference meeting in Washington.

## COURT HEARS HARDWOOD CASE

WASHINGTON, Oct. 10—Argument in the Memphis hardwood case involving the principle of the open price competition plan, which is of interest to the automotive trade, was heard by the Supreme Court this week.

## Safety Council Hears Automotive Speakers

Sessions Also Given Over to Discussions by Rubber Section of Organization

BOSTON, Oct. 10—The meetings of the automotive and rubber sections of the National Safety Council which were held in this city drew a larger attendance than many of the other sessions of the council. The tenth annual congress was held at the State House where all the big committee rooms were turned over to the organization. Three days were devoted to the sessions.

Chairman Robert A. Shaw, Ford Motor Co., Detroit, called the automotive meeting to order. Two papers were presented, J. A. Dickinson, Bureau of Standards, Washington, speaking on "Fundamental Principles of Safeguarding," in which he gave deductions from Government investigations, and E. W. Dodge, Abrasive Co., Philadelphia, talking on "Why Grinding Wheels Break."

### Kaems, Automotive Chairman

The next day there were four speakers, all of whom explained phases of conserving life and limb in big plants. The speakers and their topics were: W. J. Pfefferley, Detroit, Square D Co., "Electric Hazards and Proper Installation"; T. Alfred Fleming, New York fire insurance expert, "Fire Prevention"; David J. Price, Bureau of Chemistry, Washington, "Dust Explosions"; and A. L. Kaems, Simmons Co., Kenosha, Wis., "Punch Presses—Designs of Dies."

The closing session had the following program: "Industrial Surgery and First Aid" by Dr. T. A. McCann, Dayton Engineering Laboratories; "Safety Through Motion Pictures," David S. Beyer; and "Standardization of Statistics," George H. Hawes, Detroit.

The election of officers resulted as follows: Chairman, A. L. Kaems; vice-chairman, E. E. Blank, Buick Motor Co., Flint; secretary, M. K. Averill, Dodge Brothers, Detroit.

### Rubber Section Meets

Chairman E. H. Fitzgerald, Federal Rubber Co., Cudahy, Wis., called the rubber section to order. More than 30 rubber companies were represented. In the absence of Secretary Ray N. Watson, Goodyear, S. M. Schott, Morgan & Wright, Detroit, read the paper, "Standard Statistics on the Rubber Industry," prepared by Watson. It was followed by a talk by F. H. Hoxie on "Fire Hazards and Static Electricity in Rubber Plants." The second session had three speakers whose topics were "Safety—From a Chemist's Standpoint," by Dr. Lothar E. Webber, Boston India Rubber Laboratory; "Keeping a Rubber Factory Clean," by William S. Jameson, Fisk Rubber Co., Chicopee Falls; "Practical Plans for Medical Supervision in Rubber Plants," by Dr. R. S.

Quimby, Hood Rubber Co., Watertown.

The final session had as the principal speaker President C. D. Whittlesey, Hartford Rubber Works, who talked on "Safety—From a Factory Manager's Viewpoint." There was also a talk on "Reclaiming Plants and Their Efforts Toward Safe Operation," by John C. W. Baker, Rubber Regenerating Works, Naugatuck, Conn.

Committee reports were followed by an election of officers resulting as follows: Harold T. Martin, Fisk Rubber Co., chairman; C. F. Horan, Hood Rubber Co., vice-chairman, and E. W. Beck, United States Rubber Co., secretary.

## May Continue Cadillac Plant for Collins Car

NEW YORK, Oct. 10—Notwithstanding the fact that R. H. Collins has assumed the presidency of the Peerless Motor Car Co. of Cleveland and will take over the active management of the plant, it is possible the development of the new Collins car will be continued in the main building of the old Cadillac plant at Detroit which was purchased by Collins soon after he left the General Motors Corp. It can be stated upon authority that W. C. Durant personally retains his original interest in the development of the Collins car and would like to see it closely allied with his line. Two very fine six-cylinder cars developed by the Collins engineering staff are now running.

It is probable several changes will be made in the present Peerless organization, although it is understood that some of the present executives of the company will remain under the Collins regime. The present Peerless car will be redesigned, but it is understood few important mechanical changes will be made and that attention in this connection will be centered upon body design.

## Close Quality Plant Awaiting Inventory

INDIANAPOLIS, Oct. 10—N. M. McCullough, an Anderson banker who recently was appointed in the Federal Court at Indianapolis receiver for the Quality Tire & Rubber Co. of Anderson, has taken charge of the company's property and has closed the plant pending an inventory. McCullough qualified by filing a bond of \$10,000, which, it is understood, covers the personal property, and another bond will be required when the real estate is ordered sold.

### ALL A. E. A. SHOW SPACE TAKEN

CHICAGO, Oct. 10—When the exhibit of the Automotive Equipment Association opens at the Coliseum here Nov. 14, in connection with the annual convention of the association, all available space will have been subscribed and a splendid exhibition assured. This year attendance at the show for the afternoons of at least two days will be compulsory on the part of delegates to the convention. The show will continue to Nov. 19.

## Bull Bondholders Entitled to Proceeds

Supersede Claims of General Creditors to Share in Sale of Assets

INDIANAPOLIS, Oct. 8—Final disposition of the assets of the Bull Tractor-Madison Motors Corp. of Anderson, bankrupt, has been made by Harry C. Sheridan, referee in bankruptcy, in a ruling that Charles H. Jocknus of New York and John F. Green of St. Louis are entitled as bondholders to the proceeds from the sale of the property of the corporation. Hearing on the claims of the bondholders and of general creditors has been completed before the referee. The amount of the fund that has been held in the Union Trust Co. by Fred C. Dickson, trustee in bankruptcy, is \$120,000, practically all of which was claimed by Jocknus and Green.

The referee heard the claim of J. W. Sandsbury and the National Exchange Bank of Anderson that they were entitled to part of the fund through implied contracts, even though Jocknus and Green were conceded to be bona fide bondholders. Their claim was for about \$20,000. The Citizens Savings & Trust Co. and Wilbur M. Baldwin, trustees, of Cleveland, claimed \$6,400. The referee decided that the claims of the bondholders superseded the claims of those creditors whose claims, he ruled, were general creditors' claims.

Bankruptcy proceedings were filed against the Bull Tractor-Madison Motors Corp., with property in Anderson and Minneapolis, in July, 1920. The trustee in bankruptcy sold the assets of the corporation in November to Goldstein Brothers of Philadelphia. The plants of the corporation have not been operated during the time of the litigation. Settlement of the title to the funds held by the trustee in bankruptcy closes the case, except the formal orders to be made by the referee.

## Pennsylvania Meets to Form Association

HARRISBURG, PA., Oct. 10—At a conference here of forty delegates from all leading cities of the State, preliminary steps were taken toward organizing the Pennsylvania Automotive Association, the completion of which will be effected at a convention in the Representatives' Chamber at the State House on Nov. 9 and 10. Gov. William O. Sproul will be invited to attend and invitations will be extended to all branches of the industry in the State.

George G. MacFarland of Harrisburg was appointed temporary chairman at the conference and L. W. Schriener, a jobber of automotive merchandise, temporary secretary. The directorate will be unique inasmuch as each local association will have a representative on it.

## Branches Replacing Willys Distributors

### New Sales Policy Effective Nov. 1—Expect 7,000 Dealers in Few Months

TOLEDO, Oct. 10—Announcement of the details of the plan by which Willys-Overland Co. will completely reorganize its organization for distribution so as to give more profit to dealers and establish direct contact with factory was made here Saturday.

The plan will become effective Nov. 1.

Not more than twenty-five of the old distributors who have made remarkable records for efficiency in the selling of motor cars will be kept under contract by Willys-Overland, Inc., the great distributing corporation subsidiary to the factory company.

In the future all Willys-Overland dealers will deal directly with the factory through branches of Willys-Overland, Inc.

#### Better Service Planned

President John N. Willys has devised this new means of meeting the public's demand for cars at pre-war prices in the face of the increased cost of doing business on the part of the dealer. Through the elimination of the middleman's profit both buyer and dealer will benefit, he states.

The close connection with the factory, he says, assures the buyer the most economical and efficient service for his motor car.

"Excepting the securing of the Knight motor franchise, and the development of the Willys-Knight motor, which permits the sale of Willys-Knight cars at moderate prices, I consider this new sales plan the greatest achievement in the history of the Willys-Overland Co.," declared Willys.

"Fortunately, Willys-Overland, Inc., is well-equipped to put into effect the new sales plan at once.

"In 1916-17 a series of branch houses were built in the larger cities of the country at a cost of millions of dollars. In addition long term leases were secured on a number of excellent properties. Thus we are fortified with well organized branch houses to give rapid service, which is so essential today.

"We have anticipated the demand on the part of the public that the middleman be eliminated. It is a part of the movement back to normalcy.

#### For Better Sales Balance

"Moreover, the time has come when a truer balance of sales between various sections of the country should be maintained. We believe that sales reflect service and that by making possible to dealers in every city, town and hamlet the same factory-supervised service we can expect our products to be distributed in better proportion than in the past.

"All dealers in the United States sold slightly more than 1,800,000 automobiles last year, an average of little more than thirty cars to the dealer. In some states the sales per dealer were as low as eleven cars, in others the average sales were as high as sixty cars.

"Analysis shows that in many cases there

is a wide difference in sales per dealer in territories despite parallel conditions in crops, general financial power and living standards.

"Some states forged ahead and others fell behind. Sales of automobiles in Indiana last year increased 47 per cent compared with 22 per cent the preceding year, while Ohio sales increased only 22 per cent with 24 per cent the preceding year.

"Our investigations prove conclusively that sales are now measured largely by service rendered. We believe the new plan fills the need for our company."

The reorganized plans, calling for improvement of service and parts department sales for dealers, is looked to increase the Willys-Overland family of dealers to 7,000 in a few months.

The Willys-Overland, Inc., branch at Toledo will have under its direct jurisdiction more than 400 dealers where it formerly was limited to a field of a few counties. This will mean that the branch here will have to maintain highest efficiency to serve the dealers. The condition here is typical of the many other large branches of the distributing company.

President Willys says he looks forward  
(Continued on page 745)

## Fergusson, Engineer, Leaves Pierce-Arrow

BUFFALO, Oct. 8—David Fergusson, for many years chief engineer of the Pierce-Arrow Motor Car Co., has severed his connections with that organization and is reported to be planning an extended vacation. It is probable that the company will not appoint a successor. Delmar G. Roos, formerly assistant chief engineer of the Locomobile Co. of America, has been named passenger car engineer. E. R. Fried, formerly with the General Motors Co. and more recently chief engineer of the Murray Motor Car Co., becomes car chassis engineer.

## Ladd Metric System Bill Before Senate Committee

WASHINGTON, Oct. 11—Hearings on the Ladd Metric System bill are scheduled to begin to-day before a subcommittee of the Senate Committee on Manufactures, consisting of Senators McNary of Oregon, chairman; Weller of Maryland and Jones of New Mexico.

The first witnesses to appear will give testimony in support of the measure. Among them are Dr. Harvey W. Wiley, former chief of the Bureau of Chemistry; Dr. Charles L. Parsons, secretary of the American Chemical Society; Howard Richards, Jr., secretary of the American Metric Association; S. L. Hilton, president of the American Pharmaceutical Association; William J. Scheffelin, a drug manufacturer of New York, and Theodore H. Miller of the De Laval Separator Co.

The names of those to appear in opposition to the measure have not been announced. The bill provides for the compulsory adoption of the metric system throughout the country after ten years.

## Inventive Genius Is in Wide Demand

### Manufacturers Alert for Innovations Which Will Give Superiority to Their Product

DETROIT, Oct. 10—Inventors and students in the automotive field have never had a better opportunity to reach the ear of the manufacturer than at present. Scarcely without exception, each manufacturer has all faculties keenly observant for any improvement or innovation which promises to give his car a superiority over its fellows as to serviceability, driving qualities or general design.

Although there is a great deal of secretiveness attached to moves of this kind, many factories have their engineers testing out ideas, a number of which, it is certain, will be adopted. Nothing epochal is expected, but a very well defined line of improvements may be looked for in the cars exhibited at show time.

Simplification of the driving apparatus is one of the ideas under careful consideration, the factories knowing that any improvement making the car safer and easier to drive will increase its popularity immensely and add largely to the field of prospective buyers. It is realized that apparent complication of driving mechanism has kept many prospects from becoming actual owners.

The elimination of the human element in every possible way is being sought so far as it is possible to have mechanism replace it. Top, curtain, wheel and other incidental troubles of other years, though narrowed down to a fine minimum in cars of recent manufacture, will probably witness a still further drawing of the possible trouble line in the new cars.

Many of the medium and lower priced cars will be seen carrying improvements which up to the present have been confined largely to the higher priced automobile. No sales point that can be put into the car will be neglected.

## New Company Formed to Make Wilcox Truck

MINNEAPOLIS, Oct. 8—The Wilcox Trux, Inc., is the outcome of the reorganization of the H. E. Wilcox Motor Car Co., which on April 2 went into the hands of a receiver, F. E. Satterlee. The receiver has brought order out of chaos quickly, the creditors receiving 30 cents. The receivership shortly will be discharged. The liabilities approximated \$500,000 and the book assets \$600,000.

The new company will engage in general machine shop work as well as the construction of Wilcox trucks. The authorized capital is \$300,000. Officers are: President, H. E. Wilcox; vice-president, C. B. Will; secretary, M. H. Boutelle; treasurer, G. W. Lewis. R. D. Wilcox is an additional director.

## Automotive Bankers Form Association

### Country Wide Organization Will Serve as Clearing House for Information

CLEVELAND, Oct. 10—Representatives of approximately 100 financing companies attended the convention at which the National Association of Automotive Bankers was organized here last week. They represented an annual volume of business of more than \$500,000,000 in the United States and Canada. Members estimated that 65 per cent of the motor vehicles sold in the United States are purchased on the deferred payment plan.

Analysis of the business of the companies showed that the average purchaser is buying a car valued at approximately \$1,300; that he pays more than 50 per cent in cash; that his annual income is in excess of \$4,000; and that his net worth is in excess of \$6,000. More than 70 per cent of the purchasers have bank accounts and carry life insurance. The average purchaser is 33 years old and 75 per cent are married.

#### Headquarters in Cleveland

The headquarters of the association will be located in the Gotham National Bank building in this city and it will be incorporated in this State as a membership corporation. The organization will be carried into each state and the state branches ultimately will pay for the support of the association on the same basis as those affiliated with the National Credit Men's Association.

The main purpose of the organization is to prevent frauds by unscrupulous automobile dealers who frequently attempt to get two or three companies to finance the same motor vehicles. The association will serve as a clearing house for information valuable to the members and it will attempt, so far as possible, to put into effect uniform systems of accounting with standard financial statement blanks for dealers.

The directors elected were: Fred E. Barrett of Indiana, president of the Indianapolis association; F. A. Weber, Jr., of New York, former president of the New York association; John B. Perlee of Illinois, former president of the Chicago association; H. N. Ritter of Ohio, G. P. Hopkins of Maryland, G. A. Pivrotto of Pennsylvania, H. Abbenseth of New Jersey, H. B. Jackson, president of the New York association, and Walter E. Heller, president of the Chicago association.

#### Weber Chosen President

The directors elected Weber president, Barrett first vice-president, Perlee second vice-president, Jackson treasurer, and Ritter secretary.

Various activities, helpful not only to financing companies but to dealers, were explained by representatives of various

local associations. For example, it was stated that all the Ford dealers in Chicago have united in a plan to prevent car thefts. Each dealer places on every car a secret number and secret letters. When a car is stolen the police look for these secret identification marks and they are able through the dealers to trace the factory engine number even though it has been obliterated by the thief. In this way they are able to establish ownership. By means of this system the percentage of stolen cars recovered has been very large.

## Philippines Imported 3,835 Cars Last Year

WASHINGTON, Oct. 10—The annual report of the Insular Collector of Customs for the Philippine Islands shows that 3835 automobiles were imported during the year 1920, the cost of which was 9,038,156 Philippine dollars. The number imported in 1919 was 2557, valued at 5,947,075 Philippine dollars. Almost all of the automobiles imported came from the United States, the number being 3829, at an aggregate value of 9,017,298 Philippine dollars. One was imported from the United Kingdom, valued at 3403 Philippine dollars, and five were brought from France, at a total cost of 17,455 Philippine dollars.

Importations of automobile parts reached the value of 1,843,678 Philippine dollars. Most of these parts were bought from the United States, insignificant quantities having been purchased from Japan, the United Kingdom and France. The only countries from which automobile tires were brought were the United States and the United Kingdom.

## Three New Models by Commerce Motors

DETROIT, Oct. 8—The Commerce Motor Car Co. has three new models coming through, a bus body for the Model T chassis, a Model 18 chassis with longer loading space and 5000 lb. pay load capacity, and a "Store-At-Your-Home" truck, which is in fact a body carrying a small grocery store stock in bins. The bus body, capable of carrying 13 passengers, with equipment of 34 x 4½-in. cords, sells for \$2,300, including the Model T chassis. The new Model 18 sells for \$2,150 in chassis, and the "Store-At-Your-Home" for \$2,250. A refrigerator may be added for \$90 additional.

## Another Price Reduction Is Made on Nash Models

KENOSHA, WIS., Oct. 13—Another reduction in prices on all models of the Nash Four effective at once is made by the Nash Motors Co. The prices follow:

	Old Price	New Price
2 passenger roadster....	\$1,175	\$1,025
5 passenger touring....	1,195	1,045
Coupe .....	1,735	1,645
Sedan .....	1,935	1,835

Another reduction in prices on this line was made July 2.

## Crop Values Govern Truck Investments

### Well Developed Road Systems Im- portant Factor in Commercial Vehicle Registration

NEW YORK, Oct. 10—Investment in motor transport and high value products go hand in hand, according to comparison of Government figures on crops and motor vehicle registration on farms, as made by the National Automobile Chamber of Commerce. Iowa, Texas, Illinois, Missouri, Kansas and Ohio are among the first ten states leading in value of farm products and are also among the first ten leaders in farm motor vehicle registration.

Iowa is the banner state both agriculturally and in motor transport, being the first in value of farm products and farm-owned cars, third in average value of crops per farm and number of farm-owned motor trucks, and second in percentage of farms owning cars.

The registration of motor trucks on farms totaled 131,551 as of Jan. 1, 1920, with registration of commercial vehicles heaviest in Pennsylvania and New York where there are well developed road systems as well as a heavy truck gardening business. The corn belt states are leading purchasers of motor trucks, but their demand is small in proportion to the number of farms.

Many farms use more than one motor vehicle per farm. The Bureau of the Census count shows 2,146,512 passenger cars on 1,979,564 farms and 139,169 trucks on 131,551 farms. Cars are owned by 30.7 per cent of all farms, with 2 per cent owning motor trucks.

The Bureau of Public Roads reported a gain as of Jan. 1, 1920, of 22 per cent in the registration of all motor vehicles during the year 1920. If the farm registration increased in this ratio, the farm registration of motor cars to-day is 2,618,744 and of motor trucks 169,786. Sales reports of car manufacturers, however, indicate that the heaviest sales for 1920 were in rural regions so that the general ratio is probably too light for the farm sections, and the total of motor cars and trucks on farms may be as high as 3,000,000.

## Highway Council Head Is Now with Autocar

WASHINGTON, Oct. 10—S. M. Williams, chairman of the Federal Highway Council which is discontinuing its highway activities, has associated himself with the Autocar Co., Ardmore, Pa., as special representative. Williams began his highway work with the organization of the Highway Industries Board during the war. Following the disbanding of the board he formed the Federal Highway Council, which in the last few years has been active in developing store-door delivery, studying sub-soils of highways, and backing useful legislation.

## Tire Manufacture Continues Increase

### More Stocks on Hand for August —Volume of Shipments Greater

NEW YORK, Oct. 10—Statistics compiled by the Rubber Association of America on tire production, shipments and inventory for the Department of Commerce show a steadily increasing volume of manufacture and also an increase in stocks on hand for August as compared with July. The figures by months since November, 1920, which was taken as the base month, up to September follow:

PNEUMATIC CASINGS				
1920	Inventory	Production	Shipments	
Nov. ....	5,880,016	649,742	806,023	
Dec. ....	5,508,380	506,111	1,327,153	
1921				
Jan. ....	5,319,605	703,430	965,417	
Feb. ....	5,193,018	819,892	1,073,756	
Mar. ....	4,597,103	1,163,314	1,614,651	
Apr. ....	4,527,445	1,651,418	1,785,951	
May ....	4,451,668	2,100,917	2,085,882	
June ....	4,154,456	2,313,265	2,643,850	
July ....	3,892,037	2,570,524	2,757,581	
Aug. ....	3,934,583	3,043,187	2,894,442	

INNER TUBES				
1920	Inventory	Production	Shipments	
Nov. ....	6,131,935	742,815	920,938	
Dec. ....	5,786,929	508,446	1,481,285	
1921				
Jan. ....	5,586,163	740,824	1,042,617	
Feb. ....	5,415,464	916,627	1,129,881	
Mar. ....	5,044,861	1,346,483	1,643,690	
Apr. ....	4,916,772	1,762,122	1,983,571	
May ....	4,751,880	2,210,040	2,342,567	
June ....	3,835,098	2,359,928	3,232,673	
July ....	3,122,815	3,020,981	3,603,248	
Aug. ....	3,649,319	4,430,152	3,804,060	

SOLID TIRES				
1920	Inventory	Production	Shipments	
Nov. ....	298,875	21,355	34,217	
Dec. ....	303,473	16,297	40,828	
1921				
Jan. ....	303,753	21,220	29,116	
Feb. ....	304,374	23,365	29,599	
Mar. ....	283,800	28,710	43,926	
Apr. ....	269,985	28,859	42,080	
May ....	264,633	35,156	40,122	
June ....	240,336	38,395	49,867	
July ....	220,003	35,123	55,678	
Aug. ....	216,367	55,694	66,866	

"Production" and "Shipments" figures cover the entire month for which each report is made. "Inventory" is reported as of the last day of each month.

"Inventory" includes tires and tubes constituting domestic stock in factory and in transit to, or at, warehouses, branches (if any), or in possession of dealers on consignment basis, and as a total represents all tires and tubes still owned by manufacturers as a domestic stock.

"Shipments" includes only stock forwarded to a purchaser and does not include stock forwarded to a warehouse, branch, or on a consignment basis, or abroad.

## Employment Increases in Southern States

ATLANTA, Oct. 10—Concrete evidence that general business conditions in Atlanta and throughout the sixth Federal Reserve district, which comprises the Southeastern area, are at the highest mark since the first of this year is furnished in the monthly statement issued by the Federal Reserve Bank of Atlanta for September. All lines of wholesale and retail trade show material improvement.

The boom in cotton prices is given as the main reason for the general bet-

terment of business over the Southeast, and the bank predicts a further rise in cotton prices during October. Increases in employment are shown in the principal industrial centers of the section. Among Atlanta dealers and distributors of motor cars and trucks this betterment is being felt in increased demand, especially in the rural districts. As a whole, however, the improvement will not be felt by the automobile business in the section for at least two or three months. Especially is this true of the higher priced cars.

September bank clearings in Atlanta were almost \$30,000,000 larger than clearings during August.

## River Rouge Works on Four-Day Week

### Further Reduction in Time at Ford Foundries Scheduled for November

DETROIT, Oct. 10—Indications of a gradually decreased production by Ford Motor Co. and the allied Ford interests for the winter months are seen in the notice issued to workmen in the Ford foundries at River Rouge of a four-day week for the balance of October and a three-day week for November.

All of the Ford foundry work is now done at the River Rouge plant, the foundry at the Highland Park plant having been discontinued the past month and the transferral of equipment having been made to the Rouge. With a slowing down in business, activities are being cut down all along the line. The foundries, being the starting point of all construction, are the first affected.

### All Employees Retained

Although no formal announcement of the Ford retrenchments or of its winter manufacturing policy has been made, it is known that under its plans practically all employees will be kept on the rolls through its part time system. No complete cessation of work is expected, business conditions being far more satisfactory than a year ago.

In most of the other plants, aside from the makers of higher priced cars, much the same manufacturing policy will be carried out. Sales in higher priced cars are keeping the factories at close to 100 per cent production, and this activity promises to extend to the first of the year, and probably until spring.

Several of the medium priced cars and one low priced car are also well sold up into the future. Briscoe, soon to give way to the Earl, is said by the factory to be sold through 1922. Rickenbacker, with its promised 12,000 production in 1922, is also practically assured of a sell-out by business already received. Chevrolet is said to have enough business on its books to carry it through to August, 1922. Buick and Studebaker are also declared sold well into the future and Dodge Brothers is going steadily ahead on its 550 a day schedule.

### Equalizing Inventories

Those factories which have made curtailments in working schedules have done so to equalize inventories as work progressed and the employee organization is being kept in mobile order so that it can be quickly summoned to meet any sales requirement. No particularly dull period is expected during the winter months and everyone will be kept working, part time at least.

The care of the factories in holding together their employee organizations testifies to the general excellence of the men now working in the industry. There has been no time in recent years when the class of worker was of higher grade.

## Export Statistics Are Reclassified

### Chassis and Complete Vehicle Divisions Are Supplanted by Price Classes

WASHINGTON, Oct. 12—Export statistics of automotive products issued by the Bureau of Foreign and Domestic Commerce, have been reclassified and beginning with Jan. 1, 1922, will be listed in more detailed divisions than heretofore. The new classifications will be such as to render the statistics of considerably greater value to the industry in analyzing markets and planning sales campaigns in foreign countries.

Cars, trucks, tractors, airplanes and tires are among the chief automotive products to undergo reclassification. Heretofore exports of cars have been listed as to number and value, the divisions being chassis and complete vehicles. This classification has been of relatively small commercial value to the industry. The new divisions, however, will be one of price classes. Thus the monthly export figures of cars, beginning next January, will be listed under the three following classifications by number and value:

1. Under \$800.
2. Over \$800 and under \$2,000.
3. Over \$2,000.

#### Different Truck Listing

In accordance with this reclassification, there will be no distinction made between chassis and completed vehicles. Such distinction, however, is of practically no importance, according to prominent members of the industry who make extensive use of the figures.

Trucks will be listed according to rated capacity. The following classifications will be used, number and value being given in each case:

1. 1 ton and under.
2. 1½ tons to 2½ tons inclusive.
3. Over 2½ tons.

Under the new system there will be a separate classification of electric vehicles, while trailers will also be listed separately according to number and value.

Tires will be classified and listed in detail under the new procedure, the divisions being as follows:

1. Pneumatic casings for automobiles.
2. Other pneumatic casings.
3. Pneumatic tubes for automobiles.
4. Other pneumatic tubes.
5. Solid tires for automobiles and trucks.
6. Other solid tires.
7. Tire repair materials.

#### Aircraft Amplified

The aircraft export statistics will be amplified by the following groupings:

1. Airplanes and hydroplanes.
2. Other aircraft.

Under the present procedure all aircraft is bulked together under one general head.

The reclassification of these vital export statistics is being carried on under the direction of John Hohn, chief of the statistical division of the Bureau of Foreign and Domestic Commerce. The new and more detailed grouping of automotive products was determined upon at a conference of the statistical division and the new automotive section of the Bureau. The reorganized bureau is undertaking similar reclassification of export statistics in many lines and when completed plans for next year are announced there will be shown between 700 and 1300 new classifications of export statistics, each designed to aid directly and practically the American manufacturer in selling his foreign markets.

## BANK CREDITS

Following upon the recent announcement of increased prices for certain steel products, come further data supporting the belief that the iron and steel industry, as regards production at least, has reached the approximate bottom. The United States Steel Corporation's report of unfilled tonnage, as of Sept. 30, shows an increase for the first time since July, 1920. The unfilled orders on the books as of that date were 4,560,670 tons, an increase of 28,744 over the previous month, and is indicative of the increased rate of production as compared with shipments. The Steel Corporation's subsidiaries were working at 38 per cent of capacity at the close of the month, it is estimated, as against 30 per cent on Sept. 1. The country's pig iron production for the month of September showed an increase for the second consecutive month. The output for the month amounted to 985,529 tons, or at the rate of 32,850 tons per day as compared with an average daily output in August of 30,780 tons. There were 12 more furnaces in blast on Oct. 1 than there were a month previous.

Dun's and Bradstreet's latest index numbers again indicate a relative degree of stability in prices. For the fourth consecutive month, Bradstreet's index number increased. The increase during September was .92 per cent as against .41 per cent in the previous month; while Dun's index number showed a decline of only .48 per cent as against .66 in the previous month and an increase of 2.41 per cent two months ago.

There was little change in the Federal Reserve System's technical position last week. The reserve ratio duplicated the high for the year made the previous week, at 69 per cent. Gold reserves of the system increased \$6,633,000, while deposits declined \$21,073,000, and Federal Reserve notes in circulation increased for the first time in some months by \$25,117,000. The decline in interbank borrowing was indicative of a more uniform distribution of the improvement which has been characteristic of the system in recent months.

## G. M. Graham Resigns from Pierce-Arrow

### Becomes Chandler Vice-President in Charge of Sales, Service and Advertising

BUFFALO, Oct. 13—George M. Graham, one of the most prominent figures in the automotive industry, has resigned as vice-president of the Pierce-Arrow Motor Car Co. to become vice-president of the Chandler Motor Car Co. in charge of sales, service and advertising. He will assume his new duties Nov. 1. Graham, who formerly was a newspaper man, has been the spokesman of the industry on many occasions because of his ability as an orator. He also is an analyst and economist of note.

During the war Graham served as chairman of the Motor Truck Committee, making his headquarters in Washington. He appeared frequently before various divisions of the War Department, committees of Congress and the War Industries Board, obtaining recognition and concessions for the automotive industry.

#### Prominent in N. A. C. C.

Graham has addressed meetings of automobile dealers throughout the country, telling them of the achievements of their industry. Thousands of copies on his address on motor vehicle regulation before the National Highways Convention were distributed throughout the country. He has spoken before the Chamber of Commerce of the United States and numerous other national organizations.

Graham is a member of the highways, motor truck and taxation committees of the National Automobile Chamber of Commerce. He was one of the two spokesmen who discussed problems of the industry with President Harding last spring and he recently has appeared in Washington several times in connection with hearings on pending legislation.

After leaving the newspaper business, Graham was associated with publicity, advertising and promotion campaigns for such companies as White, Packard, Pierce-Arrow and Mitchell. When he decided to devote all of his time to the automotive industry he joined the Willys-Overland company and from there went to Pierce-Arrow five years ago. He explains that a desire to associate himself with a quantity production company producing popular priced and high grade cars prompted him to join the Chandler company.

#### TO ACCEPT STANWOOD OFFER

NEWARK, Oct. 13—Vice Chancellor Backes has authorized Receiver John P. Kirkpatrick of New Brunswick to accept the offer of \$60,000 for the assets of the Stanwood Rubber Co., made by a committee of the company's creditors, representing 85 per cent of the claims against it, and the company is to be reorganized for business.

## Engineers Witness Ordnance at Work

Almost Every Form of Equipment  
Demonstrated at Army Association Annual Meeting

ABERDEEN PROVING GROUNDS, ABERDEEN, MD., Oct. 10—Several hundred engineers representing the membership of the Society of Automotive Engineers and the American Society of Mechanical Engineers were guests of the Army Ordnance Association at its third annual convention at the proving grounds here and witnessed one of the most comprehensive demonstrations of ordnance apparatus ever staged. A program was carried out that continued from 9 o'clock in the morning until 8 in the evening and embraced a demonstration of almost every form of ordnance equipment from the 16-inch 50-calibre army gun that throws a shell weighing 2340 pounds 50,000 yards to the smallest machine gun.

### Proves Field Day

The demonstration of motorized ordnance proved a veritable mechanical circus, embracing every form of vehicle that pulls ordnance or transports ammunition. The tanks, motorized gun mounts and motor trucks had a field day over the rough proving grounds. The following is a list of motorized equipment participating in the event:

- 75 mm. gun and 105 mm. howitzer motor carriage.
- 155 mm. gun and 8-inch howitzer motor carriage.
- 75 mm. gun and 105 mm. howitzer motor carriage.
- Self-propelled caterpillar, Mark VII.
- Self-propelled caterpillar, Marks I, III, IV.
- 2½, 5 and 10-ton caterpillar tractors towing gun carriages.
- 2½-ton divisional tractor.
- 20-ton tractor.
- Peoria reconnaissance tractor.
- Syracuse reconnaissance tractor.
- Millitor truck with Chase track-laying attachment.
- Tanks in all sizes.
- Christie tank.
- White chassis with British belt track-laying attachment.
- Manly hydraulic transmission truck.
- 3-ton Christie trailer
- Cleveland 1½-ton trailer.

### Foreign Vehicles Inspected

A 75-mm. gun on caterpillar was driven through 5 ft. of water, the vehicle having a waterproofed engine and transmission. Practically all engineers present were given an opportunity of riding on the different types of vehicles. In fact, it was the wish of the army association that all guests make a trip on the apparatus.

Following the tractor circus was an inspection of German, French and Italian motor vehicles that are housed in a commodious building on the proving grounds. These consist of trucks, tanks, trailers, steam vehicles, everything, in

fact, considered worth while by the ordnance department.

The exhibition of guns and the firing demonstration were most elaborate. Everything in the ordnance category was demonstrated by firing, from the big gun to the smallest Browning machine gun. An opportunity was given the guests to look minutely into all of the gun mechanisms. There were exhibitions of firing small guns with tracer bullets, demonstrations at night with flashless powder in 75 mm. guns, and in short, a most complete demonstration of every type of gun.

Airplane demonstration was largely confined to examination of Martin bombers and Handley-Page machines. During the day the Handley-Page dropped a 2000-pound bomb on the proving grounds in plain view. Smaller bombs were also dropped. An opportunity to examine in detail the navy blimp C2 was afforded.

## Branches Replacing Willys Distributors

(Continued from page 741)

to 1922 as the greatest automobile year in history.

"A survey of the situation indicates the possible need of between 2,000,000 and 3,000,000 cars for replacement during the coming year," he declared.

"Up to January, 1921, figures show that 11,839,483 motor vehicles had been built in the United States since 1899. Of this number 613,695 had been exported. Registrations in 1920 amounted to 9,211,295. In other words, since records of automobile production were first tabulated 2,014,483 cars were worn out or discarded.

"In 1919 some 596,969 were discarded. This is very close to the actual number of cars built in 1914, the actual figure being 569,045.

"Now let us compare the discarded cars in 1920 with the production in the fifth year preceding. In 1920 some 517,556 cars were discarded as against 892,000 built in 1915. It is apparent that financial stringency and the holding back of the public on account of falling prices resulted in 374,444 cars being carried over.

"In 1916 the first huge volume production was accomplished. In that year 1,583,617 cars were built. It seems probable that the first six months of this year will see the replacement of about 1,000,000 cars, the other half million cars normally ready for replacement being carried over for the same reasons as those in 1920.

"Now in 1917 were built 1,868,947 cars.

"This figure added to the normal total of cars held over and not replaced in 1920 and 1921 gives a total of 3,000,000 cars which the records of past year show would normally come in for replacement under normal conditions in 1922.

"Even if sub-normal conditions continue we should have the greatest year for replacement in history."

Willys pointed to the manufacturing economies of his company and declared that the increasing efficiency of the last ten months was enabling Willys-Overland to give a better value than ever before.

G. B. McNary, formerly in charge of the branch at Sacramento, has been made head of the Willys-Overland, Inc., office in Dallas.

## Appeal to Harding on Sales Tax Plan

Representatives of Automotive  
Industry Endeavor to Obtain  
Support for Smoot Bill

WASHINGTON, Oct. 10—Speaking for the National Automobile Chamber of Commerce, C. C. Hanch, executive vice-president of the Lexington Motor Co. and chairman of the taxation committee of the N. A. C. C., has made a personal appeal to President Harding to use his influence in fulfilling the Administration's pledge of tax relief for American business. He directed the attention of the President to the fact that coteries in Congress were menacing economic recovery and characterized the tax plan as now proposed by Senate and House as "mere fly specks in the business situation."

### Hanch Sends Letter

The automotive industry in common with many other manufacturers sent its representatives to a White House conference in a final effort to obtain the support of the President to the proposed manufacturer's sales tax plan known as the Smoot bill. The opinion of American business men as represented in the manufacturers' national tax committee was made known by John E. Edgerton, president of the National Association of Manufacturers.

The industry was represented at the conference by Hanch, J. Walter Drake, president of the Hupp Motor Car Corp., and Pyke Johnson, Washington representative of the N. A. C. C. The visit was followed by a letter to the President signed by Hanch as chairman of the tax committee of the N. A. C. C. Mention was made of the fact that many legislators believe that a manufacturers' sales tax is inevitable.

### Seek Just Taxes

In his communication to the President, Hanch made clear the thought of the industry on tax revision. He said:

"At this moment your administration is plagued by cliques and blocs in Congress which are the direct outgrowth of existing class legislation. The continuance of repressive war measures during times of peace will inevitably create a riot of class rivalries, class hatreds and class laws.

"Aside from the proposed repeal of transportation taxes all of the other proposed repeals of discriminatory war taxes are but mere fly specks in the business situation. How much simpler and better it would be if the Congress would accept your constructive recommendation to 'abolish inequities' by the repeal of all special discriminatory stigma war taxes and the substitution thereof of an equitable manufacturer's tax. Many congressmen who fear an equitable tax at this time unhesitatingly say that such a tax is inevitable later on.

"In view of the foregoing we respectfully suggest the propriety of your reminding Congress again of the necessity in the public interest for 'the abolition of the inequities and unjustifiable exasperations in the present (taxation) system.'"

## October Expected to Maintain Pace

### Value of Sales Will Probably Be Higher Because of Enclosed Car Demand

NEW YORK, Oct. 12—While it is probable sales of passenger cars will decline somewhat this month from the total for September, there is every indication that the volume of business will not show a large shrinkage. It would not be surprising if it was found that the next 30 days were approximately as good as the past thirty.

Notwithstanding the unsettling effect of a large number of price reductions, shipments of automobiles in September were only 4 per cent less than in August and it is significant that they were 85 per cent of September, 1920. It is probable the October total will equal or exceed the total for October last year and that comparisons from then on will show a balance favorable to each current month. While predictions are unsafe in a period of deflation and readjustment, there appears to be little danger in asserting that so far as the automotive industry is concerned the worst is over.

### Higher Priced Cars Gain

The slight falling off in business last month was in the lower and medium priced cars, and almost without exception the companies making cars in the higher price classes had material gains in business. Orders for high priced cars continue to come in on a basis which indicates that the September gain in sales will continue this month.

Production schedules for October have been curtailed in only a few instances although production will be kept strictly to a sales basis and accumulation of surplus cars in the hands of dealers or in warehouses will not be permitted. The largest decline in car production last month was in the Ford plant where the total was approximately 90,000. The company expects to produce an equal number of cars in October, but if there is a sharp falling off in orders, of which there is no indication at present, this output will be curtailed.

### Truck Market Improves

The indications are that while the actual number of cars sold in October will be smaller than in September, the aggregate value will be higher because with the slackening of demand for touring cars there will be an increased sale of enclosed models, which are all in a higher price class. Almost without exception, body builders are running close to capacity on enclosed models, and dealers report an exceptionally strong demand for cars of this class.

One of the most gratifying features of the situation to-day in the automobile field is the increased call for motor trucks. Sales of light delivery trucks have been better for several weeks and

## "JITNEY" DISCARDED; IS REPLACED BY "BUS"

NEW YORK, Oct. 10—The motor truck manufacturers of the country propose to take the "jit" out of jitney. In fact, they are opposed to the use of the word at all and will use all the influence they have to bring about the substitution of motor bus or just plain bus. They believe "jitney" has come into bad repute and the public generally misunderstands the term. A good many people who would be glad to ride in a motor bus shun the jitney in the belief that it is likely to be a converted ice wagon.

they now are extending into the heavy duty field. This is an unmistakable indication that general business is improving and that the larger volume of freight makes necessary an extension of transportation facilities.

## Gustafson New Manager of R. & V. Motor Co.

EAST MOLINE, ILL., Sept. 21—Discontinuance of the Moline Engine Co., proposed taking over of the poppet valve business by the Moline Plow Co. and recent sale of a portion of its properties to the Troy Laundry Machine Co., have necessitated changes in personnel of the R. & V. Motor Co.

Executive staff and directorate of the company remains unchanged with H. A. Holder president, but G. L. Walker of East Moline, assistant secretary and treasurer, becomes assistant to the president, and Gust Olson is elevated to chief engineer. A. A. Gustafson is made general superintendent or works manager directing assembling of chassis, plant maintenance, tool room and stores, machine shop, test and inspection.

D. M. Beal, who has been assistant sales manager, assumes responsibility for the finished car, a department which embraces chassis test, painting, trimming, assembly and final test. Department executives continue unchanged.

## Firestone in Alabama Surpasses War Times

BIRMINGHAM, ALA., Oct. 10—As a barometer of the improved conditions in the automobile industry in the local field the branch office of the Firestone Tire Co. here has done a larger business in the past ninety days than it did during the peak of the war days, and with a smaller sales force. This, according to P. D. Mingledorf, manager of the branch, is due to the fact that more cars are moving now than have been moving at any period since last December and also to the fact that farsighted dealers, seeing the rush coming with prosperity's return, began stocking up long before the crest of the hard time wave had passed.

## Plan of Lafayette Is 100 Cars Monthly

### Schedule Will Continue Through Fall and Winter With Increase in Spring

INDIANAPOLIS, Oct. 10 — The Lafayette Motors Co. of this city is celebrating the completion of the first year of production with a convention of distributors here. According to data given out by Charles W. Nash, president of the company, to the men attending the meeting, 800 Lafayette cars have been shipped to distributors and more than 700 are now in the hands of owners. Since May 1 orders at the factory have run approximately 100 ahead of production and, on the basis of present orders and the feeling among distributors, plans have been laid for the steady production of 100 cars a month during the fall and winter, with a large increase in the spring. The productive capacity of the plant as it is now is ten cars a day. Nash and officials of the company are confident of reaching this mark in 1922.

The Lafayette company now is represented by thirty direct distributors, a large percentage of whom handle the Lafayette in conjunction with the Nash. While the production for the first year falls considerably short of the mark set, Nash considers the record a good one, inasmuch as the industrial depression set in almost simultaneously with the shipment of the first car from the plant in 1920.

With only minor details, the chassis has not undergone change during the first year and no change is expected. One new body style, a roadster, has been added, and Nash states that there may be other body styles to satisfy any justifiable demand.

## Case Against Buffalo Broker Is Dismissed

INDIANAPOLIS, Oct. 10—Charges of extortion, preferred against John B. Porter of Buffalo, N. Y., who recently filed charges of grand larceny against Newton VanZandt, former president of the Revere Motor Car Corp. of Logansport, have been dismissed by authorities at Erie, Pa., where the case was filed, according to information received here. Porter was arrested in Logansport several weeks ago on the charge. At that time he was in the city to testify before the Cass County Grand Jury in connection with an investigation into the rumors and allegations concerning the Revere corporation.

### SHERMAN VISITS LOUISVILLE

LOUISVILLE, Oct. 8—Ray W. Sherman, merchandising director of the Automotive Equipment Association, was the principal speaker at the meeting of the Louisville Automobile Dealers' Association.

## Car Makers Urged to Give More Help

Used Cars, Financing and Contracts, Subjects Considered at  
N. A. C. C. Meeting

(Continued from page 736)

Shale contended that the automotive industry cannot be placed upon a really solid foundation until the manufacturer assumes a greater share of the dealer's financial burden. He pointed out the large volume of sales made on the deferred payment plan and held that unless business was continued on this paper there would be a large falling off in sales. This was his advice to the manufacturer:

### Shale's Suggestions

"Your margin to the dealer should be sufficient to enable him to give a cash discount, allowing him to receive a like discount from you if he pays in cash, or allowing him to pass this installment paper to you in settlement of his obligation at par, with legal interest added. The manufacturer can at all times have a reserve set up for this cash discount, either to be taken by the dealer when settlement is made in cash or to provide you with a fund that will enable you to use this reserve to sell the installment paper to produce cash.

"I believe it is essential that the manufacturer should be the pivot point through which this paper should be handled, so that the sales by his dealer will be readily taken care of. This would be in lieu of your giving the dealer unsecured credit.

"The manufacturer, in establishing new distribution, should require that his dealer have sufficient capital to carry his stock for all display purposes, necessary parts for service and take care of his selling expenses, to the period when his profit begins to come back to him by reason of these sales on the installment plan, which in the ordinary case would be about six months."

### Schumann's Contentions Similar

It was also the contention of Schumann that manufacturers should bear a greater share of the burden. He said that an investigation made by his company disclosed that banks in the Central West and New England preferred truck paper to passenger car paper, but that on the Pacific Coast the reverse was true.

In the discussion of the used car problem some of the suggestions made were:

That all used cars be reconditioned before they are sold and given the same backing by the dealer that he gives to new cars. This would inspire confidence on the part of prospective purchasers and bring many new prospects into the market. It was felt that every purchaser of a used car was a potential purchaser of a new one.

That dealers establish co-operative repair shops where used cars could be reconditioned instead of each dealer maintaining his own shop.

That each dealer assign his best salesmen to the task of selling used cars instead of leaving it to the "cubs."

That each salesman be compelled to find a purchaser for every car he takes in a trade.

That there be a co-operative advertising campaign on the part of the manufacturers to promote the sale of used cars. There was a sharp division of sentiment on this question, however, and it seemed to be the general idea that each manufacturer should work with his own dealers in advertising used cars.

As a result of the discussions, the N. A. C. C. will make an investigation of markets to determine in what way dealers can best be helped and educated.

Contract changes proposed by the committee representing the N. A. D. A., which has had two sessions with a special committee appointed by the N. A. C. C., were explained to the members. They were discussed at some length and the N. A. C. C. committee was authorized to hold another session with the N. A. D. A. representatives. This meeting will be held next week in Detroit.

Some of the contract changes proposed by the dealers probably will be accepted by the manufacturers, but not all of them. No matter what recommendations are made by the N. A. C. C. committee it will be impossible to carry them into effect except through their acceptance by each individual manufacturer.

There is a general feeling on the part of the vehicle builders that some of the unsatisfactory conditions which existed when the two committees were appointed already have righted themselves and that these readjustments will continue automatically. They assert that the attitude taken by factory sales managers is less arbitrary than in the past and that relations with dealers will become increasingly closer in the future.

### NOMA PRICES CUT

NEW YORK, Oct. 8.—The second reduction in 60 days has been announced by the Noma Motor Corp., manufacturer of Noma cars. The change made is as follows:

	Old Price	New Price
Roadster .....	\$2,800	\$2,500
4 passenger touring....	2,850	2,550

The prices are f.o.b. factory, plus war tax. No change has been made in the prices of the other models.

### INCREASE FOR NATIONAL

INDIANAPOLIS, Oct. 8.—The National Motor Car and Vehicle Corp., manufacturer of the National has increased the prices on its sedan and coupe as follows:

	Old Price	New Price
7 passenger sedan.....	\$3,990	\$4,240
4 passenger coupe.....	3,990	4,140

There is no change in the prices of other models. All prices are f.o.b. factory.

### TRACTORS REDUCED

CHICAGO, Oct. 8.—The Emerson Brentingham Co. has made a reduction of 10 per cent in the price of tractors and 20 per cent in that of farm implements.

## Price Reductions Spur Texas Trade

Liquidation of Accounts Contributes to Improvement of  
Automobile Business

DALLAS, Oct. 11.—While no figures are available as to the exact number of automobiles sold by Dallas dealers during the month of September the dealers themselves declare the business was as good as that during the preceding months when sales records for the past eighteen months were hung up. Practically every dealer in Dallas reported business brisk with sales getting better. They attribute the improved business in the automotive trade generally to more money in circulation and the customers, actual owners or ultimate consumers of all lines having more confidence in the financial stability of the period.

Lower prices of cars coupled with marketing of the cotton and grain crops and the placing of that money in actual circulation through liquidation of accounts are the actual reasons for better automobile business in this section. The farmers are marketing cotton at prices that have enabled them to pay accounts and have something left. The automobile dealers have not overlooked this and as a result sales have been made. Scores of persons who have bought cars in Dallas during the past month have been waiting for reductions along pre-war lines. When those reductions came the selling began in earnest.

As during the preceding month, the normal priced cars led in sales. High priced cars, however, were going right along and dealers said the outlook was brighter. Indications are now that the total automobile business in Dallas this year will amount to \$225,000,000, which is a considerable increase over the business for the past year.

Truck and tractor men reported better business, especially with the farmers. A great number of trucks, tractors and trailers have been shipped out of Dallas to the farmers of the wheat belts of Texas, Oklahoma and the cotton belts of these two States and Louisiana and the ranchers and cattlemen of Texas and New Mexico during the past month.

### NEW SOCIETY FOR ENGINEERS

NEWARK, N. J., Oct. 8.—Realizing the importance of co-operation in the development of friction drive, now becoming a recognized factor in many industries, a number of prominent engineers have formed the Friction Drive Engineering Society. Temporary officers have been elected as follows: President, C. A. S. Howlett of Divine Brothers Co., Utica, N. Y.; vice-president, W. D. Hamerstadt of the Rockwood Mfg. Co., Indianapolis, Ind.; secretary and treasurer, C. W. Kelsey of the Kelsey Motor Co., Newark, N. J.

## INDUSTRIAL NOTES

**S-P Mfg. Co.**, Cleveland, has purchased the former American Air Chuck Co. of Chicago. The work of re-establishing the business is well under way and with the aid of J. A. Colson, inventor of the American company's product, who will be associated with the S-P concern, the product will be ready for the market within a short time. The regular business of the S-P company has consisted of the design and manufacture of special machinery, fixtures, jigs, tools, etc., a line that will be continued and, as the demand increases, additional equipment will be installed for the manufacture of the air devices. The company plans to develop further the use of air power equipment for production to replace the hand methods of chucking work and similar operations.

**Victor Rubber Co.**, Springfield, Ohio, earned a profit of \$62,030, during July and August, according to President H. S. Berlin, and in addition set aside \$36,781 as a reserve for unanticipated contingencies. Thus far this year the production of the plant has been doubled by installing improved methods in manufacture; operating costs have been substantially decreased and the sales for the twelve months will be the largest of any period in the company's history, Berlin says. The number of sales agencies will be doubled. The directors of the company have declared the quarterly dividend of 1½% payable Oct. 25, on all preferred stock.

**Kendall Tire & Rubber Co.** and **Arlston Tire & Rubber Co.**, Massillon, Ohio, have been placed in the hands of W. S. Adams, receiver, on a petition of the First National Bank of Louisville, which claims \$22,000 on notes given by the two companies. **Fidelity Tire & Rubber Co.** of Illinois, which has been operating the plant by lease, is made a party to the action. The bank holds that its claim is secured by mortgage on the machinery and equipment of the companies and that the use of this material under lease to the Illinois concern lessens its value. Judgment on the note and foreclosure of the mortgage are asked.

**Bush Mfg.**, Hartford, Conn., manufacturing airplane, truck and tractor radiators, has purchased the property of the Ellison Construction Co. in that city, comprising a tract of three acres improved with a factory building, storage house and gasoline station. Continued growth of business in recent years has made the removal of the Bush company from its present location in the city necessary.

**Moline Plow Co.**, recently organized by a creditor's committee, plans resumption of business at its Rock Island plant, the Universal Tractor Co., early in December. Two hundred former employees of the tractor branch will be placed at work. In order that its warehouse stock may be disposed of a new work started, the company, at a loss, will reduce the price of all farm machinery.

**Quaker City Rubber Co.** of Philadelphia, manufacturer of Quaker tires and tubes, reports that its factories have been busy the entire year. At the main offices of the company the demand for space for the officers and salesrooms has been so great that it has been necessary to erect a new building at 624 Market Street, Philadelphia, which will be occupied Nov. 1.

**St. Louis Pump & Equipment Co.**, St. Louis, engineers and manufacturers of gasoline and oil handling units for filling stations, has acquired a location at Forest Park Boulevard and Spring Avenue, that city, and

will centralize its general offices and plants there, the new location providing facilities for largely increased production.

**Massey-Harris Implement Co.** will open a plant in Australia for the manufacture of tractors. The company produced \$6,000,000 worth of machinery for Australia last year. The new Australian tariff has closed the commonwealth to outsiders and it becomes necessary to set up a plant there in order to hold this trade.

**White Motor Co.** has increased its production schedule 20%, inventory for certain models of trucks having been reduced to such an extent that greater production was necessary. September sales of the company were 8% better than August, a month that was 10% better than July.

**Mikesell Bros. Mfg. Co.**, which occupies the former plant of the Perfection Tire & Rubber Co. at Wabash, Ind., is working full force, the only local industry on such schedule. The company manufactures brake linings, fan belts and other automotive equipment.

**Chevrolet Brothers Manufacturing Co.**, organized by Arthur and Louis Chevrolet, will soon occupy its own building, Louis Chevrolet has announced. The company will manufacture Frontenac cylinder heads and also will do machine repair work.

**J. G. Riggs & Sons Co.**, Springfield, Mass., handling automotive equipment, has opened its new building in that city constructed especially to suit the needs of the jobber. The company maintains branches in Pittsfield and Holyoke.

**Goodyear** sales for the first nine months of the year exceed those of the same period last year, during which the first six months sales were the greatest in the history of the company, according to President E. G. Wilmer.

**Moon Motor Car Co.** reports that September sales for this year were 33% greater than sales for the same month in 1920. Business was not spotty, the cotton situation adding substantially in an increased demand in the South.

**The Racine Rubber Co.** of Racine, Wis., has removed its sales department to New York. The company is a subsidiary of the Ajax Rubber Co.

**Charles H. Harris**, Norwalk, Conn., has completed a factory in that city for the manufacture of high grade plate glass for automobiles.

Farmers Oppose Plan  
for Trade Commission

WASHINGTON, Oct. 11—Proposals originating within the administration for the abolition of the Federal Trade Commission have provoked widespread comment. It is understood the plans call for closing up the affairs of this Federal agency before June 30, 1922, if possible. Members of the commission are entirely familiar with the arrangements.

It is understood to be the purpose of the administration to reorganize the commission with a view to consolidating it with the Department of Justice. Opposition to the proposal has arisen among the farm organizations and they have appealed to the "agricultural bloc" in the Senate to prevent it if possible. It is contended in some quarters that the commission has become a persecutor of business rather than an aid in rehabilitating industry.

## METAL MARKETS

THE character of recent price changes in the steel market furnishes the key to the proper interpretation of whatever alteration quotations may undergo during the year's remainder. From all that can be learned about the sheet orders now on the books of producers the preponderating bulk was placed at the recent low level, and the \$5 a ton advance, ample notice of which was given to every possible buyer, merely served as a magnet to bring out business at the old figure. The tonnage of sheet orders placed at the advanced prices is so negligible a one that it furnishes very little succor to the mills. Undoubtedly a good many sheet consumers just came in under the wire with their orders before the advance went into effect, but some of the smaller producing interests appear not to have been unduly exacting as to the time limit for acceptance of orders at the old prices. This past record, together with the plentitude of prophecies of higher prices for this or that steel product, which market reporters encounter these days, permit of the conclusion that whatever predictions of price advances will be launched into market reports in the next three months will be in the nature of efforts to bring out business at the old prices. Moreover, there will be far more predictions of price advances than actual raising of price levels. In fact, there are still a few commodities in the finished steel list that will very likely come in for reductions as a more direct means of inducing buyers to place orders. As the application of the Eastern trunk line railroads for permission to reduce freight rates on iron ore by 28 per cent, which was made to the Interstate Commerce Commission, has been granted the price of iron in the Pittsburgh district should eventually be cheapened by about 75 cents a ton and in the Schuylkill valley district by about \$1.25. It remains to be seen whether reductions in freight rates, which are confidently looked for all along the line, will result in immediate savings to consumers or whether, for a time at least, the revenue which the railroads will forego will wander into producers' pockets. Eventually, of course, competition will adjust this problem.

**Pig Iron.**—Automotive foundries are buying in a routine way only. Additional furnaces are contemplating resumption and October production will very likely pass the million-ton mark. With the elimination of surplus offerings by steel mill furnaces the merchant market is becoming more and more steady.

**Steel.**—Demand for full-finished automobile sheets is easing off as the result of seasonably lessened production schedules of passenger car builders. The same condition holds true of the strip steel market, although the Buick Motor Co. has recently figured as a fairly large purchaser of cold-rolled strip steel. The market for alloy steels lags, but producers hope for broader demand from refinements in 1922 passenger car models.

**Aluminum.**—On the surface there appears to be but little change in the situation, German 98 to 99 per cent ingots having been offered in the last few days at as low as 17c., duty paid, and a tonnage of French metal being hawked around the market at a similar price level, provided the entire lot would be taken. These offerings, however, appear in the light of clearance sales.

**Copper.**—London's opinion of the recent advances in the copper market are of interest. That market ascribes the advance solely to manipulation. There is no question that consuming buying here has broadened.

## MEN OF THE INDUSTRY

William M. Chamberlin has been appointed to the sales department of the Maxwell Motor Sales Corp. and Chalmers Motor Car Co. He will be concerned with the development of better merchandising methods. Chamberlin has been connected in various capacities with the Wright Mfg. Co., Detroit; Wilder Tannery, Waukegan, Ill.; Irving National Bank of New York, Detroit Lubricator Co., and Detroit Twist Drill Co. He was also president of the Chamberlin Co., a technical advertising agency.

J. A. Gelzer, Chicago, formerly associated with the Wagner Electric Mfg. Co., St. Louis, has been appointed sales manager of the Hoosier Clutch Co., Muncie, Ind. Gelzer is a university graduate in mechanical and electrical engineering and has been associated with the Wagner company for the past fifteen years, the last eight of which were spent in the automotive branch of the company's business as manager of sales in the western district.

J. H. Greer has been appointed manager of the Kansas City branch of the McGraw Tire & Rubber Co., succeeding W. S. Chambers, resigned. Greer has had 14 years' experience in the tire business. During this time he had served as branch manager for several prominent tire companies, among them being the United States for whom he functioned as branch manager at Kansas City.

Dr. Walter E. Boveri has arrived in New York to make a study of business conditions in this country. Boveri is a member of the Swiss electrical engineering firm of Brown, Boveri & Cie., which has important affiliations in many European countries, and which also controls Scintilla Société Anonyme of Soleure, Switzerland, and the Scintilla Magneto Co., Inc. of New York.

W. H. Richardson, manager of the Chicago branch of the Bearings Service Co., has been transferred to the managership of the New York branch. Frank J. Lemper will succeed him. Lemper is a mechanical engineer and a graduate of the University of Michigan. Previous to his present appointment he was connected with the Detroit branch of the company.

T. M. House, Spokane, has taken over the distribution of Rugles trucks for the Pacific Coast territory. He was formerly Western sales manager for the Republic Motor Truck Co. with jurisdiction over the Pacific Coast and later served as general manager for the company.

George H. Phelps, advertising manager of Dodge Brothers, has sailed for England aboard the *Aquitania*, accompanied by Russel Huff, chief engineer, to look over the company's British and continental business.

Victor Gauvreau, for the last four years chief engineer of the Pan Motor Co., St. Cloud, Minn., has joined the staff of the University of Minnesota as instructor of gas engines and machine design.

J. G. Anderson, president of the Anderson Motor Co., Rock Hill, S. C., has started on a six weeks' trip which will take him as far west as the coast visiting company dealers and distributors.

Herbert R. Hyman, for seven years advertising manager of the Cole Motor Car Co., Indianapolis, has become associated with Charles H. Fuller Co., advertising agency in Chicago.

J. Walter Drake, chairman of the foreign trade committee of the National Automobile Chamber of Commerce, has been elected a

director of the American Manufacturers' Export Association.

F. H. Dolbeer, formerly treasurer of the Willys-Overland Co., Toledo, has been made traveling sales manager of the Victor Talking Machine Co., with headquarters at Camden, N. J.

S. W. Reese, formerly representative of the Oldfield Tire Co. in the Kansas City district, will succeed H. T. Roseland as branch manager in that territory for the Star Rubber Co., Akron.

## FINANCIAL NOTES

General Motors Corp. probably will make a better financial showing for the full year than was expected a few months ago. Definite figures for the third quarter have not been completed, but the fact that shipments were as large as in the second quarter, if not larger, indicates that the profits will approximate those of the June quarter. The company is getting constantly increasing benefits from its improved inventory position.

Durant Motors has been granted permission by the securities department of the Secretary of State's office of Illinois to resubmit its statement for filing, which, if filed, will carry with it the right to offer its securities in the State.

Black & Decker Mfg. Co., Towson Heights, Baltimore, builder of portable electric tools, has declared a dividend on outstanding preferred stock for the third quarter this year amounting to 2 per cent, or 8 per cent per annum.

Chevrolet Motor Co. has declared a dividend of 3 per cent on its capital stock, payable Nov. 2 to stock of record Oct. 15.

Service Motor Truck Co., Wabash, Ind., has redeemed \$137,850 worth of preferred stock.

Packard Sets Record  
in Argentine Contest

BUENOS AIRES, Sept. 17 (By Mail) —The swiftest kilometer ever run by an automobile in South America was made by the winner of the kilometer championship of the Automovil Club Argentino, recently held here on the La Plata road and competed for by a field of 27 drivers. The championship was awarded to Alejandro Schoega, who drove a Packard car over the measured kilometer in 21.6 seconds or at the rate of 166-2/3 kilometers an hour. In this, he bettered by practically six seconds the time made in 1918 by Juan Bonamaison, who won the last kilometer championship held by the club. The rate in that race was 130.67 kilometers per hour.

Schoega's victory was in the unlimited class, in which he was pitted against six other cars of North American, French, German and Argentine manufacture. Other categories were of cars limited in cylinder displacement to three, four, five and six liters. In the various classes, victories were scored by the Sunbeam, Wolseley, Poto, Nash, Hudson and Cadillac, cars of the latter makes placing first in two races.

Earl Specifications  
Differ from BriscoeProvide for Smaller Engine and  
Longer Wheel Base on New  
Product

JACKSON, Oct. 10—Closely following on the heels of the change in name of the Briscoe to the Earl comes the information that the new car, which will also bear the name of Earl, will be very much different from the Briscoe.

The engine is four-cylinder block cast, 3 7/16 x 5 1/4 in., a little smaller than the Briscoe. It has a three-bearing crankshaft, splash lubrication, and thermo-siphon cooling. A 10-in. Borg & Beck dry plate clutch will connect the engine with the three speed gearset. The semi-floating rear axle, with spiral bevel gear and pinion, will be arranged for Hotchkiss drive. New Departure ball bearings will be used on the pinion shaft and Hyatt roller bearings in the differential and rear wheels; 14-in. brake drums are fitted on the rear wheels, and an emergency brake is mounted on the transmission.

The 7-in. frame has five cross members and semi-elliptic springs; 36 in. long in front, 56 in. in the rear. The steering gear is of the worm and gear type and a 17-in. steering wheel with horn button top is fitted. The car has 112-in. wheelbase; I-beam front axle with Timken roller bearings in front wheels, is used.

Artillery-type wood wheels with demountable rims are standard equipment, but wire wheels are provided at extra cost. Cord tires, 32 x 4, are standard equipment, straight side. An 18-gal. gasoline tank is mounted at the rear, with vacuum feed to carburetor. Color: touring car, Lake green, with black top, fenders and chassis. Genuine pebbled grain leather upholstery. Nickel-plated radiator shell, lamps, bumper and trimmings. Linoleum covered floor boards. Equipment includes electric side lights, Motometer, windshield wiper, tonneau foot rest, etc. Color: roadster, optional, with choice of upholstery; same equipment as touring car. Color: sedan and brougham, Ultramarine blue. Equipment includes cowl ventilator, sun visor, rear view mirror, running board step mats, interior dome light, heater and silver plated metal trimmings.

John N. Willys Buys  
Estate Near Toledo

TOLEDO, Oct. 10—John N. Willys has purchased a 100-acre estate up the Maumee Valley from Toledo, a distance of about five miles. He plans to build a 30-room residence. It is expected this will mean that Willys plans to spend a large portion of his time each year in Toledo.

Willys recently sold to Arthur Bell, bond broker, Toledo, his city property, which was valued at \$1,000,000. The new up-river home is in a group of large estates.

# Calendar

## SHOWS

Nov. 14-15—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association, Fourth Regiment Armory.

Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Grand Central Palace, Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Feb. 6 to 11—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.

Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

Oct. 5-16—Paris, France, Paris Motor Show, Grand Palais, Administration de l'Exposition Internationale de l'Automobile, 51, Rue Pergolèse, Paris.

Oct. 10-22—Olympia, England, Truck Show, Nov. 4-12—Car Show, Nov. 23-Dec. 3—Motorcycle Show.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

November 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.

Nov. 26—Dec. 3—Shanghai, China, Automobile Show.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador, Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibits in connection with the Brazilian Centenary Association Automobilista Brasileira.

## CONVENTIONS

Oct. 12-14—Chicago, Twenty-eighth Annual Convention National Implement & Vehicle Ass'n.

Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Dec. 6-8—Chicago, Second Annual Meeting of American Petroleum Institute.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

Jan. 17-20, 1922—Chicago, American Road Builders Association.

S. A. E. MEETINGS  
Detroit, Oct. 21, Nov. 18, Dec. 23, Feb. 24, March 24, April 28, May 26.

New York, Jan. 10-13, 1922—Annual Meeting.

## Seager Invention Sustained by Court

### Webb Jay System Infringed, Opinion Says in Suit Brought Against Stewart-Warner

(Continued from page 737)

"All of the functions which are ascribed by the defendant to the Stewart-Warner Webb Jay system, over and above Seager and Harrington, are functions resulting solely from additions to, and not departures from the combination of Seager's and Harrington's claims.

"Insofar as the record shows, no one prior to Seager recognized the usability of the suction produced in the intake passageway of an internal combustion engine as a source of power. Certainly, no one prior to Seager in any way applied that power to lifting fuel from a low level tank to an elevated auxiliary reservoir, from which the carbureter might be supplied independently of the level of the fuel in the main storage tank.

"Seager may have failed to claim the broader concept of applying that suction power to every kind of work outside the intake passageway, but certainly the means claimed by him for raising the fuel to an elevated auxiliary reservoir, and then discharging it to the carbureter of the engine, was new and entitled to broad protection.

"I have been urged to resolve any doubts in favor of the defendant, because the plaintiff's device has never been sold to the automobile trade, and because of the enormous investment made by defendant in putting its device on the market. This plea would be important if I were in doubt as to the validity of Seager and Harrington. However disturbing defendant's plea in this behalf has been, I must still bear in mind that whatever the power and activity of the defendant may have been in the past, it has been shown not only that Seager's invention is applicable to automobiles, but also that the defendant's device is applicable to stationary engines.

"As early as 1914 Seager was brought to the attention of the defendant when the Patent Office cited Seager in anticipation of claims made in the then pending application of Webb Jay. The Seager interests then opened negotiations with the defendant,

which proved to be fruitless. At that time the defendant resolved all doubts in its favor. In that it was wrong."

## Will Appeal

CHICAGO, Oct. 12—Stewart-Warner Speedometer Corp. will appeal from the decision handed down in the United States District Court by Judge Carpenter in the suit of Seager, Payton & Thomas against Stewart-Warner, alleging infringement of automobile engine vacuum gasoline feed patents obtained by James B. Seager and Norman T. Harrington. It is said that the Stewart-Warner corporation has sold approximately 5,000,000 vacuum systems at \$10 each. In the absence of C. B. Smith, president of Stewart-Warner, no other statement than that the decision would in no way interfere with the dealer organization could be secured.

According to T. T. Sullivan, vice-president of the corporation, the tanks will continue to be manufactured, pending an appeal, and in the event that the higher court should decide unfavorably a very slight change in the construction of the tank will be made.

## Gold Plaques Given Seiberling Brothers

AKRON, Oct. 10—Officials and employees of the Goodyear Tire & Rubber Co., Ltd., of Toronto, Canada, have presented to Frank Seiberling, founder and former president of all Goodyear companies, and to his brother, C. W. Seiberling, handsome solid gold plaques bearing inscriptions of tribute and respect.

Set in frames of purple plush, the plaques which are about six inches square are handsomely emblazoned with the American and Canadian flags, the American eagle and Canadian beaver. The border is of Canadian maple leaves, handcarved in gold.

The presentation of the plaques was made on Frank Seiberling's birthday on Oct. 7, and on the eve of his return to the rubber industry as a magnate controlling and operating a potentially strong chain of small rubber companies.

## Farmers Hold Back for Price Reductions

### Further Cuts Necessary, N. I. V. A. Members Told, in Order to Induce Buying

CHICAGO, Oct. 12—Members of the National Implement & Vehicle Association who are attending the 28th convention of the organization here were told to-day by C. L. Glasgow, representing the National Federation of Implement & Vehicle Dealers Association that farmers will not buy machinery at present prices, which represent a reduction of only 15 to 20 per cent from the war level. He urged implement manufacturers to cut prices now and take their losses, thereby getting ready for 1922 business. If this is not done, he declared, 1922 will witness a heavy mortality among dealers. Glasgow asserted that the buyers' strike of the farmers is still on and attributed it to the manufacturers' failure to cut prices.

The attempt of implement makers last spring to increase prices 10 per cent was very unwise, Glasgow contended, because it antagonized farmers who have loaned machinery to each other this year rather than buy new. As a result, the warehouses of implement makers are filled with unsold implements. Only a reduction in price will start the farmers buying, he said.

## GRANT HAS NEW TOURING BODY

CLEVELAND, Oct. 10—A new touring body is being fitted to the standard Grant chassis and the complete car is called the Grant Special, priced at \$1,285. The construction of the body is slightly altered from the current model, the running boards are redesigned and the fenders shaped somewhat differently. Otherwise the Special model is similar to the standard touring, which has recently had considerable special equipment added without increase of price.

# Simplified Production

## *Another Result of Concentration in Buying*

In every phase of motor car manufacture, simpler ideas, simpler processes, simpler ways of doing things are earnestly being sought. For simpler methods mean better workmanship—greater speed—lower manufacturing costs.

The installation of hardware in motor car bodies can be greatly simplified through concentrating *exclusively* in Ternstedt Automobile Body Hardware.

Every appliance, in the *complete* Ternstedt line, is so simplified—so *standardized*—that it fits exactly—*always*.

Rarely is there need for forcing or cutting, redesigning or substituting. Consequently there are no delays. Body production goes smoothly and speedily along to completion. Costs are cut to the minimum.

For this reason alone, many of the foremost motor car manufacturers and body builders are using Ternstedt Hardware *exclusively*. But, simplified production, is only one advantage; there are many others.

We sincerely believe that you will be genuinely interested in knowing them all.

## N.I.V.A. Discusses Difficulties of Farm Implement Industry

No immediate market, but future holds large possibilities. Dealers urge lower prices. Large inventories not yet liquidated by manufacturers. Power farming idea must be sold. Standardization necessary.

By David Beecroft

CHICAGO, October 15.

**T**HAT leaders in the manufacture of farm equipment machinery, which includes farm tractors, are deeply concerned because of the existing depression was evidenced by the phenomenal attendance at every session of the three-day convention of these makers which ended here to-night. The National Implement and Vehicle Association, which counts within its membership practically every manufacturer of farm equipment from pumps to binders and tractors, held its twenty-eighth convention, and company executives who have not been seen at these conventions for a dozen years were on hand and sat throughout the forenoon and afternoon sessions. Approximately 150 to 175 attended throughout each session.

The program was largely drafted to suit the present exigency, which finds our agriculture at the lowest point in its history and finds these 150 or more machinery manufacturers passing through almost a complete state of selling coma. In most lines there has been a cessation of sales which set in last November and has continued with almost unbroken regularity up to the present. Call it the farmers', buyers' strike, or label it with any other name, and the situation remains the same; namely, one which has caused

very many of the factories to remain closed for months and which has resulted in material inventories not being much reduced in the last ten months. Branch houses and machinery warehouses throughout the country are stocked to the roofs with unsold farm machinery.

These farm machinery manufacturers have had one handicap during the current year which has not been at the doorstep of many other national manufacturers: They have had the misfortune, or fortune, according as you view it, of selling to one class of customers, farmers. The motor car manufacturer has had a broad selling field, the doctor, banker, lawyer, merchant, manufacturer, contractor, broker and a hundred other classifications, but these farm equipment makers have had to concentrate on one classification, the farmer.

This exclusive character of their selling field has made the present year proportionately worse in that no other class of citizens has suffered such a cut in the price of their commodities as the farmer. It is true that the farmer came through four or five years of prosperity culminating with the 1919 crop, but, unfortunately, such years of plenty found the farmer a very ready buyer, even of luxuries, and often a poor conserver of money. The high-priced crop that

he grew in 1920 suddenly stopped the buying career of almost millions.

A year ago few of us believed that the farmer was in such straitened circumstances as a few keen students of agriculture declared existed. When he stopped buying in the autumn of 1920 his case was not taken much more seriously than that of his town and city cousin; both went on a buyers' strike. But when the farmer failed to come into the market with the warm days of spring, and when he failed to enter the market when the fields were waving with ripened harvests the concern of the manufacturer grew still more real. It has only been in the last few months that the country as a whole has realized the plight of the farmer. It is only within the last few months that the truth of the farmers' buying power has become generally understood.

Last February at the national tractor show held in Columbus, Ohio, most of the tractor manufacturers were speculating on the probable time the farmer would return to the market. Then there was no doubt but that he would come in time for the spring crop and the harvest as well. It was merely a question of when and in what proportions. As spring wore on and he did not come; when summer came and went and he still held out, then the manufacturer had a complete realization of the problem that faced him. At once there arose a painful consciousness that the industry faced the greatest problem of its history.

A pretty accurate clue to the American agricultural situation was contained in the words of Hon. Henry C. Wallace, Secretary of Agriculture, speaking before the convention, and also in the same address which he delivered to over 1000 business men, members of the Chicago Association of Commerce:

"For more than a year we have passed through a period of severe agricultural depression. It has been a trying period. The prices the farmer is getting to-day for his major agricultural commodities are considerably below the prices he received for them in the five pre-war years, 1909 to 1913, inclusive. The prices for basic commodities that the farmer must buy are still above pre-war prices. Farmers constitute 40 per cent of the population of our country and you cannot have such a terrific reduction in the prices of commodities they have to sell and keep the prices of what they have to buy considerably above pre-war prices without compelling those farmers to practise the most rigid economy. This cannot happen without all industry having to suffer, and those industries most closely related to the farm—namely, farm equipment—suffer first and most severely.

"I think it true that many forehanded farmers who had money accumulations as a result of long years of work and saving have at times been unwise in their program of economy, but the psychology of the situation accounts for it, but from this time on purchases by farmers of equipment needed will gradually and steadily increase.

"We must get back onto an even keel, and it would be far better if prices of farm products could be brought up to a fair level rather than that wages and prices of other commodities should be brought down to the present level of farm prices. One or the other must happen.

When we get on an even keel again, very likely we shall find ourselves riding on a plane of prices about 50 or 60 per cent above pre-war levels, but we would reach that desirable state much sooner and with less hardship if there were a clearer recognition of the relations of agricultural property to national prosperity."

It will assist in gaining a more comprehensive conception of the present-day agricultural situation by bearing in mind that the average purchasing power of the farmer is but 70 per cent of what it was in the five pre-war years, this figure being based on current prices of thirty-one major farm commodities. Corn states are to-day quite severely hit in that the average purchasing power of corn is 50 per cent of what it was in the five pre-war years. In this may be found an explanation of why wholesale and retail motor sales have slumped very heavily in corn territory in the last few months.

With this as the background from which to study the business outlook for 1922 for farm equipment, it is not surprising that the keenest market students of this group of makers are not deluding themselves as to the demand for next year. They are not looking for any active demand for another twelve months. These makers face the situation calmly and discuss it equally calmly. They do not attempt

to conceal the fact that there has been practically no buying this year; they do not look for much in 1922; but they are studying overtime to learn just what must happen.

Here is how some of the leaders are reasoning with regard to two or three years hence:

Basing calculations on the fact that farm machinery wears out every seven years; further, that during the last

four years purchasing by farmers has been 10 per cent less than normal; they estimate that to-day the average condition of farm machinery is only 80 per cent of normal. This, in the words of William Black, president of the National Implement and Vehicle Association and president of one of the large makers of farm equipment, "means that in two or three years there will come a season when the supply of new equipment will not equal the demand, and the longer the depression lasts the greater will be the demand.

"The manufacturer for the past year has been concerned with the problem of liquidation and that of earning profits, but he is now beginning to realize that the only way he can stay in business is to do business. The only way to make a profit is to sell goods, as without sales there are no profits."

One session of the convention was occupied by the leaders in manufacture wrestling with the problem of how better to conduct business so as to make a profit. These studies were entirely concerned with methods of finance, and the question of what volume of business you should attempt to do on a given amount of capital. In this program three of the leading manufacturers very frankly analyzed the affairs of their own businesses, and it was commendable to see a group of makers considering so openly and frankly this fundamental of business. They feel that fluctuations in business can largely be avoided by more careful studies.

It was disappointing in the convention that the big problem of reducing cost of merchandising to the farmer by virtue of reducing merchandising

---

**STANDARDIZATION** of machinery parts has not yet been favorably received by tractor and farm implement manufacturers. There are some who think, however, that the farm machinery industry is on the verge of the greatest revolution in manufacture it has ever faced. The present crisis is driving home manufacturing lessons that have not heretofore been heeded.

---

costs was not even directly discussed. The manufacturers riveted their attention too generally on financing and company economics. There was little if anything said on greater economy in factory manufacturing methods; in fact, the subject of standardization as a means of reducing costs seems still a long way off from many of these makers.

The question of lower prices and the imperative necessity for such was brought home to the convention in no unmistakable manner by a representative of the farm equipment dealers of the country. These dealers held their annual convention last week in order to be ready to lay their thoughts on the present situation before the makers this week. There was no doubting the meaning of the message they handed to the manufacturers, and in selecting Hon. C. L. Glasgow of Michigan to present it they selected a man who apparently had no fear and one whose words showed that conviction was the major reason for what he uttered.

He openly charged the farm equipment manufacturers with bad judgment when, at the opening of the 1921 season, they increased the price of their equipment 10 per cent, apparently hoping to stampede the farmer into buying on the fear of still higher prices. That has since proved to have been a very serious error. It proved so in the motor car field. It antagonized the farmer. He lost confidence in an industry that he had been dealing with since his start in farming. Since then prices have dropped 15 to 20 per cent in general, and in some instances as high as 27 per cent, but the farmer is still obdurate, and not only does not buy but is firmly convinced that prices must come still lower, and is frankly resolved that they will go still lower before he buys.

The dealers are also convinced that prices must fall, and Mr. Glasgow, speaking for the dealers, urged all manufacturers to cut prices right down and so get the farmer in a better humor for the start of 1922 business. Unless this is done there is going to be a very heavy mortality among farm equipment dealers.

The suggestion of one manufacturer that the dealer work, work, work was openly resented by the dealers, who declared that it was little use working unless the manufacturers' price program was better suited to the condition of the times. They have worked and have witnessed farmers loaning binders, seed drills, disk harrows and tractors among themselves in order to avoid buying new ones. Some speakers at the convention who are manufacturers and own farms openly admitted that they need certain farm equipment and are borrowing from neighbors rather than buying new. They are waiting for lower prices.

While the convention apparently studiously avoided any consideration of price reductions, it is certain this subject was very much discussed by groups around luncheon tables and in quiet corners of the hotel lobby during the convention. The farm equipment manufacturers have not been able to reduce inventories very much in the past year. In the summer of 1920 they walked knee deep into too heavy purchases of materials and parts. They were led into this by sales reports of tremendous orders. Few of them realized that often these sales reports represented protecting orders from

dealers who, feeling they could not get machinery from one concern, placed orders with five or six, hoping out of all to get their demands filled. Suddenly this situation appeared, but not before vastly too heavy inventories had been accumulated. These inventories are still very largely on hand, because of the almost complete cessation of buying. Much liquidation has yet to be accomplished. In the past year these manufacturers have reduced forces in many cases to mere skeletons, they have closed factories and taken other steps, and in the year ahead it is not going to be possible for them to make further reductions; they must carry on business on the positive method of creating sales.

It is still quite apparent that standardization of machinery parts as a means of reducing costs has not been favorably received by these machinery makers. Some attention was given to this subject at the convention, one speaker, E. A. White, president of the American Society of Agricultural Engineers and engineering editor of the *Farm Implement News*, read a paper on it, but, following the general rules of the convention, there was no discussion. After the close of the session one maker, perhaps unconsciously, made one of the strongest statements in favor of standardization. He spoke of how

certain materials are costing him nearly double what they used to and in the next breath gave the reason in the small orders that it was necessary for him to place. Had certain materials been standardized by specifications there would not be much necessity for short orders. The material makers could carry stocks of standard lines, being sure of certain demand for such.

There are those who think that the farm machinery industry stands

to-day on the verge of the greatest revolution in manufacture that it has ever faced. This farm machinery crisis, the worst in its history, is driving home lessons of manufacture that formerly fell too often on deaf ears. There are some of these concerns who frankly admit they have no engineering organization but have such work in the hands of a head draftsman. It is difficult for standardization to make that progress that the times demand until each concern has a properly organized engineering department. There is still too general use of castings and scrap iron. The field of the stamping and in some cases the forging lies ahead.

There must come into the industry that spirit of co-operation in manufacture that will admit of standardization which will reduce costs.

A recent example is that of a mowing attachment for cutting hay to attach to tractors. Last summer three makers, International Harvester, Cletrac and Fordson, marketed attachments in which the old conventional mowing machine was superseded by merely a cutter bar that was carried direct on the tractor, thereby eliminating the major part of the mowing machine. There was no evidence of standardizing these cutting attachments. They were attached in three different ways; in fact, three different manufacturers built the attachments. They had but one thought, namely, of building for an individual type. It is not surprising that in some cases the prices were much higher than what the farmer had been in the habit of paying for a complete mowing ma-

---

**T**HE farmer has not been overstocked with farm equipment up to this time, according to Department of Agriculture figures. There has been little business during the past year and little is likely during 1922. Wm. Black, President of the N. I. V. A., states, however, "that in two or three years there will come a season when the supply of new equipment will not equal the demand and the longer the depression lasts, the greater will be the demand."

---

chine, drawn by horses. In the babyhood of such an industry, thought must be given to standardization of such attachments, otherwise prices will not come down to the levels they should, and whenever prices are thus unsoundly maintained the manufacturer is contributing to erecting a wall of sales resistance. He is making it harder and more costly to do business.

Automotive manufacturers in general can cut a few leaves from the note books of farm equipment makers in the respect in which the latter study agriculture and make use of the Department of Agriculture. A few figures will give the outline of a picture that will stand study: Of the 6,500,000 farmers, the ownership of automotive equipment is about as follows:

Percentage of farmers owning motor cars.....	40
Percentage of farmers owning tractors.....	63.6
Percentage of farmers owning motor trucks.....	2
Percentage of farmers owning isolated house lighting plants .....	7

While the farmer has not been purchasing motor cars in the past year, there are still, according to these government figures, 60 per cent of them who yet have to purchase cars, and this in itself is a market worth studying. There is one trend that is taking place in agriculture that augurs favorably for wider buying of cars by farmers, namely, the fact that each decade finds the average size of the farm in older settled sections increasing in size, and in some of the later farm sections where too large farms have been used they are decreasing in size.

The ranks of farm equipment manufacturers are divided on just what is the best method of selling tractors. There are two schools of tractor sales; let us say two groups.

Group One has as its objective the dominant thought of selling tractors.

Group Two has as its dominant idea that of selling the power farming idea.

The two groups are widely separated in viewpoint. AUTOMOTIVE INDUSTRIES stands back of Group Two in its conception of selling. The idea must precede the machine. There has been altogether too much attempt to sell a tractor on the ground that you can plow an acre of land cheaper with a tractor than with a horse. The national tractor demonstration last summer had this fact fundamentally in mind. The motor car was never sold on the argument that you could travel two miles cheaper in a car than you can go the same distance behind a mule.

The idea of the motor car was sold whether we were conscious of it or not. It was what the car would do for the person who bought it. With the motor truck it is what the truck can accomplish by way of extending the boundaries of business and accomplishing those one hundred things that the horse and mule simply cannot accomplish.

So the school of tractor sales that has as its objective the selling of the power farming idea is going to win out. It is fundamentally sound and must win. There are today too few of the tractor makers who realize what a tractor means to a farmer. In Kansas it enables him to plow the ground in the hot days of July, when horses cannot do the job well, and thus gives a greatly increased yield of winter wheat as compared with the same land plowed in August or September.

In North Dakota it makes it possible to summer fallow in July and thus get increased yields of spring wheat.

In Illinois it enables the corn farmer to get his corn sown early in May and thus reap an increased yield.

These are facts, borne out by years of experience and attested to by scientific farmers. The tractor never will come into its own if it is just sold as a substitute for horses. So tractor sales school two is going to win out and these days of depression should stimulate its growth.

Those farm equipment manufacturers who in the halcyon war years took up the development of a line of motor trucks have not reaped the harvest visioned by them. Their business has been practically nil. It is generally conceded that it was an ill-advised move. Some of them developed too-large-capacity machines for economic farm use. They have also discovered that it calls for a different sales effort to sell trucks to farmers. The net result is that with the depression that has been rather general over the truck industry in the past year, the farm equipment makers have had no encouragement and it will not be surprising if some of them discontinue their contemplated programs. Undoubtedly the success of the International Harvester Co. had some influence on starting some of them in this field, but they may have overlooked the fact that many of the trucks built by this concern are not sold through their farm machinery dealers. There are cities where the I. H. C. has its large farm machinery branch from which it sells its farm lines, but its trucks are marketed by a dealer along automotive row or in some other suitable part of the city.

Concerning the general future of United States agriculture, there is a consensus of opinion that although the American farmer, thanks to modern machinery, produces four or five times as much food products as the European farmer, yet days calling for deep consideration of all problems are ahead. Secretary Wallace thinks that the other great agricultural nations of the world are going to play a growing part in supplying the world's needs of farm products and that our great Mississippi valley has as great if not greater farm problems ahead than it has yet faced. He favors standardization of machinery and implements and his department stands ready to assist in this work.

Up to this time the farmer has not been overstocked with farm equipment, according to Department of Agriculture figures, which show that farm equipment purchased annually represents only 5 per cent of the value of the crop. The value of farm crops for 1920 was \$9,165,348,000, and for the same year the sale of farm equipment was \$471,442,000. In agriculture man labor, power and machinery constitute 31 to 69.5 per cent of the total cost of producing crops.

There has been in demand to changing times a heavy elimination in the number of types of different farm implements in the last seventy years, as shown by the following figures. The first column shows the number of models eliminated and the second column the number retained:

Machine	Type Eliminated	Type Retained
Seed drills .....	32	18
Mowing machines .....	2	6
Disk harrows .....	53	44
Corn planters .....	759	29
Riding plows .....	32	16
Walking plows .....	179	34
Cultivators .....	165	10
Wagons .....	4,336	224

These figures do not refer to trade models but to types. One example cited as to how standardization might be carried out was that of the left-hand plow. There is nothing that a left-hand plow can do but can be done equally well with a right-hand plow. Notwithstanding this the manufacture of the left-hand design is continued

(Continued on page 772)

# Excellent Technical Papers Read at Gear Makers' Convention

Detailed program of standardization work as formulated at Niagara Falls committee meeting was ratified. Members witnessed new machines for bevel gear manufacture in operation. Two new companies were admitted to membership. Various committee reports were presented.

By P. M. Heldt

A NUMBER of excellent technical papers were presented at the semi-annual convention of the American Gear Manufacturers' Association, which was held at the Powers Hotel, Rochester, Oct. 13 to 15. In the line of standardization work, a definite program to guide the activities of the different subcommittees—which program was worked out at a meeting of the Standards Committee at Niagara Falls last summer—was ratified, with slight changes and additions in some cases. The program of the convention also included a visit of inspection to the Gleason Works, where a number of new gear cutting machines were shown the members, and a clambake at Corbett's Glen as the guests of the Gleason Works.

In the report of the Secretary it was brought out that the Association is still growing; at the time the convention opened it had 92 member companies with 110 executive and 59 associate members, making a total of 169 members. Two applications for company membership were favorably voted on at the meeting. The new companies admitted were the Central Products Co. of Detroit and the Harris Machine Co. of Bridgeport, Conn. It was announced that a foreign membership clause was to be added to the constitution for the benefit of firms in the gear business in other countries.

## Cost Accounting

J. H. Dunn presented the report of the Committee on Uniform Cost Accounting. He said that the committee had issued a questionnaire to the membership concerning their cost accounting practice, but that the returns from this had been rather unsatisfactory. President Sinram, referring to this report, said that practically all member companies were running very light and had cut their overhead expense as low as possible, so that insufficient office help might account for the fact that no more replies had been received; but as business was getting nearer to normal again all would be in need of the information which the questionnaire was to bring out, and he urged members to give the committee all possible help in the future.

The questionnaire of the committee brought in replies from 44 member companies, of which seven had less than 50 employees, 11 between 50 and 100, 15 between 100 and 500, six between 500 and 1000 and three over 1000, while two did not state the number of employees. Of these same companies 16 had adopted the Association's system of uniform cost accounting, five used a similar system and one had adopted it in part. The machine-hour rate by machine or group is used by 16 companies; one percentage of direct labor for entire plant, by 14 companies, departmental percentage of direct labor rate, by 8 companies and the productive hour rate by two. Thirty-six companies

stated that they had the totals of the amount of factory expenses to compare with the total amount distributed to cost of jobs. The following table gives a survey of the methods of distributing administrative, general and selling expenses to costs:

	Companies
Percentage of factory cost.....	22
Combined with shop overhead and distributed on a percentage of direct labor basis.....	7
Combined with shop overhead and included in machine rate .....	1
On productive hour basis .....	3
On productive labor basis.....	2
Percentage of sales .....	1
Do not keep job costs .....	1
Question not answered .....	7
	<hr/> 44

In discussing the problem of cost accounting, Geo. Markland said that his firm in making cost estimates used the machine rate basis, but doing this in obtaining their actual costs in case they were awarded the job took too much time under present conditions.

In connection with the report of the Industrial Relations Committee and the discussion thereon a warning was issued to members by one of the speakers not to take any work below cost; if they were doing so because they thought it would cut down their overhead, they were fooling themselves. Another point brought out was that if allowance is made for the increase in freight rates, steel is selling cheaper to-day than it was before the war.

## Standards Committee Report

B. F. Waterman made a report for the sectional committee of the American Engineering Standards Committee. He said that Mr. Buckingham, vice-chairman of that committee, had now in hand the preparation of a digest of all standardization work on gears that had been done in this country and abroad. A letter had been received from the German Standardization Committee asking for information on stub tooth standards. The Canadian Engineering Standards Committee had offered to co-operate with the American Engineering Standards Committee and had been asked to send a representative to each executive meeting. A copy had been received of the French stub tooth standard, based on the metric system, with a request that it be considered by the committee.

## Tooth Wear with Different Steels

A paper on Tooth Wear with Different Gear Steels, by E. R. Ross, experimental engineer of the Warner Gear Co., was presented by S. O. White, chief engineer of the same company. The intermediate speed gears of a three-

speed transmission were run under heavy load for a period of six hours and the wear on the tooth flanks was carefully measured with a micrometer caliper. Gears of different steels, both oil hardening and case hardening, were thus experimented with, and the results plotted in the form of wear diagrams. We expect to reprint this paper in an early issue. Mr. White was asked what he considered to be the best backlash between the teeth of a transmission gear; he replied that this had nothing to do with the subject of the paper, but that his company generally allowed between 0.007 and 0.008 in. backlash. It was also asked why it was that the diagrams all showed the greatest wear to occur at the pitch line, when it was a well-established fact that at the pitch line action was that of pure rolling motion. It was explained that this was due to the dwell at the pitch line, which allowed time for the oil to be squeezed out between the contacting surfaces and thus causing maximum wear at that line. A curve of temperature rise showed that the oil on the transmission case attained a working temperature of 274 deg. Fahr. in the tests, and Mr. White said that it was then about as thin as kerosene.

On Thursday evening E. S. Sawtelle, assistant general manager of the Tool Steel Gear & Pinion Co. of Cincinnati, gave a talk on a European trip made by him the past summer. He dwelt mainly on points that arouse the interest of the general tourist, but also gave some impressions of business conditions in the several countries visited and their possible effect on American export trade in the future. Mr. Sawtelle visited England, Holland, France, Switzerland and Germany.

#### Duralumin as a Gear Material

On Friday morning R. W. Daniels of the Baush Machine Tool Co. presented a paper on Duralumin as a Material for Worm and Other Gearing. Mr. Daniels first gave an outline of the history, composition, heat treatment and mechanical properties of duralumin and then discussed its adaptability to worm wheels and other types of gearing. He said in substance:

Duralumin is an ideal material for worm wheels, provided the bearing or wearing qualities are satisfactory. For a given section the weight is one-third that of the conventional bronze. The tensile strength and relative high elastic limit insure superior tooth strength. The homogeneous structure and uniform hardness of heat treated duralumin forgings insure entire freedom from hard spots, porosity and spongy areas so common in bronze castings, which entail not only machine loss but uneven tooth wear in service. The excellent machining qualities insure the manufacturer a saving in his machining costs over bronze.

The wearing qualities of worm wheels for automotive purposes is best determined by actual road service, as bench or laboratory test results do not always correspond. It is instructive, however, to compare results obtained from duralumin with those of other materials under identical conditions. The data from various laboratory tests under, the writer's observations on bronze and duralumin worm wheels may be summarized by saying that tests destructive to duralumin worm wheels were also destructive to those made of bronze. Where duralumin and hardened steel are run together the results are always good. An example of this application is shown by duralumin connecting rods running direct on the wrist-pins with better life at this point than with the conventional bronze bushed rod of equal bearing area.

Comparative tests of bearings made from duralumin against bearings made of genuine babbitt, show that for shaft speeds exceeding 700 r.p.m. and loads over 200 lb. per sq. in., duralumin bearings develop less friction, re-

main cooler and show practically no loss in weight under most severe conditions. For lower bearing pressure and lower speeds, babbitt metal is superior.

#### Tested on Fifth Avenue Buses

Some tests made by the Research Department of the Fifth Avenue Coach Co. on worm wheels of duralumin were quoted by Mr. Daniels. Three duralumin worm wheels were procured and installed in the standard worm carriers, and road tests were started on three buses (2-A type.) These wheels were inspected periodically during the first few weeks' service, and again at the time of the next annual overhaul of the buses. The results obtained with these sample worm wheels are given in the following table:

	Bus 30Z	39	40
Date in .....	8/27/20	9/15/20	9/11/20
Date removed .....	6/20/21	In Service	6/17/21
Mileage. ....	26,672	24,143	32,253
Miles per gal., aver. ....	6.75	6.52	6.65

From this it will be seen that 83,068 miles were covered with these units, all of which at the end of the period showed excellent resistance to wear along the pitch line. In the case of one unit there had been a failure of the bearing behind the worm, and the sides of this wheel were slightly chipped, but not sufficient to prevent it from being put back in service with the others. Inspection of the wheels after the above service indicated wearing qualities equal to those of the standard bronze gear wheel. In view of the advantages to be gained from the use of this material, the acquisition of several more, for a more exhaustive test, was recommended.

Examination of the lubricating oil threw an interesting light on conditions of wear. With bronze wheels, if the oil has not been changed for a long time, an examination of the oil always shows particles of bronze in suspension. This not only indicates wear, but also deterioration of the lubricating value.

#### For Gears of Other Types

The same qualities that make duralumin a desirable material for automotive worm wheels also make it valuable for plain spur and other gearing. It is suitable for this class of work where the pressures are sufficiently within its elastic limit of 30,000 lb. per sq. in. Where this condition is met, and weight and quietness are desirable, it replaces iron, steel, brass, fiber, fabric, etc. Where duralumin can be run with steel rather than against itself, the best results are obtained. An example of this application is found in the timing gear trains of automobile motors where both long life and quietness are essential.

Helical cut spur gears of duralumin alternated with steel gears have been most successful in service. Detailed test reports are not especially interesting, as the gear design varies with every motor, but the fact that upwards of 60,000 duralumin camshaft and idler gears are now in use, is conclusive.

#### Further Standards Reports

A number of reports by subcommittees of the Standards Committee were presented on Friday afternoon and evening, discussed and acted upon. Some of these contained only the program according to which the subcommittee planned to work, while others contained definite proposals in the way of standardization.

Frank E. Eberhardt presented the report of the Spur Gear Sub-Committee. In this connection it was recommended by Frank Burgess that when the committee gets to work it adopt a rule prescribing a greater face width for a pinion than for the mating gear. J. B. Foote reverted to the matter of the rule for face width, discussed

at some length at the previous meeting in Cincinnati. He said that the multiplier 9, which had been used for many years, was based on scientific considerations and should not be discarded in favor of 10, as proposed, unless good reasons for the change could be adduced. The report was adopted. The report of the Sub-Committee on Gears and Pinions for Electric Railways and Mines, presented by Chairman W. H. Phillips, was also adopted.

A Nomenclature Sub-Committee has been appointed which consists of the chairmen of all the other sub-committees. This has been collecting names, terms, symbols and formulae from catalogs, lists and books, and they are now going over these lists of terms, etc., to eliminate inconsistencies. A report of progress was made and this was adopted.

J. C. O'Brien made a report for the Sub-Committee on Worms, Worm Gears and Spirals. This committee will be known hereafter as the Sub-Committee on Worm Gears. Frank Eberhardt stated that one of the most important items in the program of this committee was the collection of data on successful and unsuccessful worm gears. After a change in the order of the items in the program the report was adopted.

#### Inspection Methods

F. G. Eppley read the report of the Inspection Sub-Committee. This also covered only the program of the work the committee plans to do, with some comments on the different items. It was noted from this report that the committee is making some efforts to obtain a standard of comparison and a means of making comparisons of gear noises. It was stated that the Bureau of Standards is now working on a method of measuring sound. In connection with this report it was pointed out by one of the members that the methods of inspection worked out would be used by customers of the gear makers, and that therefore no tests and no standards should be recommended which were of such a high order that they could not be lived up to by the members. Mr. Phillips said that his company had an inspection method for each type of gearing and other companies undoubtedly the same, and he suggested that all these data be turned over to the Inspection Sub-Committee. B. F. Waterman said that it would be necessary to differentiate between manufacturer's tests and customer's tests as regards instruments to be used, and that any test standardized must be commercial. The report was adopted.

The report of the Bevel and Spiral Bevel Gear Sub-Committee, F. E. McMullen, chairman, also was merely a program of the work to be done and was approved of by the meeting. C. R. Weiss, chairman of the Sprocket Committee, presented the report of that committee. In addition to the program for future work, this covered matters which have already been adopted by the S. A. E. and the A. S. M. E. and are therefore known. The report was adopted.

#### Special Steel Specifications Discarded

C. B. Hamilton, Jr., chairman of the Metallurgical Sub-Committee, reported for that body. This committee some time ago worked up specifications for a special screw stock, but in as much as the screw stock specifications of the S. A. E. and the A. S. T. M. are alike, it was felt that there was no need for introducing an additional specification, and this proposal was therefore dropped. In fact, it was decided to drop all of the special steel specifications of the American Gear Manufacturers' Association (known as A. G. M. A. steels) with one exception. This is the 1045 A. G. M. A. steel, which differs from the No. 1045 S. A. E. steel in having 0.30 to 0.60 per cent manganese instead of 0.50 to 0.80 per cent. Mr. Frost said that he had always objected to the No. 1020 S. A. E. steel, which has a

carbon range of from 15 to 25 points. If you happen to get practically the maximum carbon limit and at the same time high manganese content, it is impossible to properly carbonize the steel. There was some discussion as to the advisability of eliminating this steel from the list, but it was brought out that it is one of the most widely used gear steels; moreover, the proposal to use the 1015 steel instead met with the objection that with this specially low carbon steel it is hard to keep down the sulphur content. Mr. Frost said that he was not speaking from selfish motives, as his firm tested every shipment of steel it received, but some of the other firms which had no testing facilities might possibly have trouble. He suggested that if the proposed table of specifications be adopted it be printed with a foot-note warning users of the danger pointed out by him. The report was adopted as revised. Proposed brass and bronze specifications, which cover S. A. E. specifications Nos. 62 to 65 inclusive, were adopted. For steel castings the committee proposed the adoption of the specification already in use by the A. S. T. M. (Specification A-27-21), with the addition: "All gear castings must be properly annealed." This part of the report was also adopted.

In connection with the report of the Keyways Committee, Mr. Burgess made an appeal for multiple keyways, as a single key in his estimation was not sufficiently secure, but W. H. Diefendorf suggested that he use a taper on his shaft and a nut on same, in which case he would not need multiple keys. This, too, was only a progress report and was adopted. Mr. Petersen, who represented the S. A. E. Iron and Steel Division at the convention, requested that two members of the A. G. M. A. metallurgical committee be delegated to attend every meeting of the Iron and Steel Division. This request was acceded to.

#### Visit to Gleason Works

On Friday afternoon a visit was made to the plant of the Gleason Works. There J. B. Foote of Chicago spoke on some of the welfare features introduced by the Gleasons for the benefit of their employees. These included old age pensions, a dining room, a library, musical entertainments and a mutual aid society. In the factory the members inspected a number of new machines used in the production of bevel gears, including a 4-in. spiral bevel gear generator, an 8-in. spiral bevel gear generator (used among other things for the production of spiral bevel gears for driving overhead camshafts) a bevel gear burnishing machine, a 38-in. two-tool gear planer, a 9-in. two-tool gear generator, a three-spindle bevel gear rougher, a three-spindle bevel gear generator and a tool grinder for the 4-in. spiral generator.

On Friday evening the association held its banquet at the Powers Hotel. J. E. Gleason acted as toastmaster, and the speakers were the Hon. Arthur E. Sutherland, who spoke on "Capital and Labor," and Ernest Paviour, former president of the Rochester Ad Club, who spoke on "Advertising."

On Saturday morning, at the final session of the convention, E. W. Miller, chief engineer of the Fellows Gear Shaper Co., presented a paper on "Tooth Forms." Mr. Miller said that the only tooth curve which deserved consideration was the involute, but he showed that even by adhering to this curve there was a possibility of considerable variation in the form and efficiency of the tooth by changing the part of the involute to the base circle which is used. It was proven that in order to have a tooth form system which could be produced by all of the methods now extant, it was necessary to use a pressure angle of 24 deg. and a few minutes, if the whole system from a 12-tooth pinion to a rack was to be interchangeable. We expect to reprint this paper in an early issue.

# First German Automobile Show in Ten Years

Marks re-entry of German automobile industry into world competition. Some concerns book orders for year's production. Forty-six manufacturers show 90 models ranging from 14 to 75 hp. Four-cylinder and L-head engine and four-speed gearset predominate. One stock engine shown.

By W. F. Bradley

**B**ERLIN'S automobile show, the first since 1911, marks the complete re-entry of the German automobile industry into world competition. The show is held in a big hall specially built by the German automobile manufacturers for exhibition purposes, and finished just before the outbreak of war. At the same time the German makers opened their own speedway, the only one of its kind on the Continent. This has its main entrances some 200 yards from the exhibition hall. This track undoubtedly served as an immense attraction to the show. It is estimated that on the opening and following days 500,000 persons paid for admission to the speedway. On the days of the race tickets were resold privately at a minimum of 1000 marks.

Business conditions at the show were entirely satisfactory, and as a result of the exhibition many factories are booked up with orders for one year. Berlin is full of foreign buyers, who are interested, among other things, in automobiles because of the low price made possible by reason of the depreciated value of the mark. For the purpose of rough comparison the value of the mark may be taken as being equal to one cent in American currency. Sometimes it gets a little above this figure, but more often it is below. On this basis the most costly car in the Berlin show is the Maybach 90-hp. six-cylinder which, with high-grade open body and all modern fittings, is listed at \$4,300. A few other prices, selected haphazard, are as follows:

Mercedes, 6 cyl., 90 hp., open body .....	\$3,300
Benz, 6 cyl., 50 hp., open body .....	3,200
Opel, 6 cyl., 75 hp., open body .....	3,000
Horch, 6 cyl., 80 hp., open body .....	2,750

Rumpler, 6 cyl., 50 hp., open body .....	\$1,500
Rumpler, 6 cyl., 50 hp., sedan body .....	2,000
Adler, 4 cyl., 18 hp., open body .....	1,300
Adler, 4 cyl., 26 hp., open body .....	1,800
Dinos, 4 cyl., 30 hp., open body .....	1,600
Ego, 4 cyl., 20 hp., 2 seater open body .....	710
Brennabor, 4 cyl., 25 hp., open body .....	700
Bob, 4 cyl., 20 hp., 2 seater .....	620

The majority of these are really high-grade cars with excellent body work, comparable to the most costly types produced in America or elsewhere. The open six-cylinder Rumpler, for instance, is a car which would be sold in any other European country at twice the price asked on the Berlin market. Considered as a whole, equivalent models built by Italian, French, Belgian or English firms would cost 50 to 75 per cent more in American currency. In all cases these are retail selling prices in Berlin. For export business lower prices would prevail.

In the above list the only car really laid out for cheap production is the four-cylinder Brennabor, designated as 25 hp. This power, in common with others quoted above, is really the actual power of the engine, an equivalent rating in other European countries being 10 to 15 hp.

Germany is in a position to challenge the world with medium and high grade cars which are cheaper than those of any other nation by reason of the depreciated value of the mark. There has been very little attempt as yet to get down to low prices by simplified design and cheap production methods, as they are known in America. One of the reasons for this is that the home market is very small, and the foreign market being varied, it is difficult to select one type which will be successful for a wide range of

Germany's new building used exclusively for automobile show purposes and known as Kaiserdamm Palace

countries. Another reason is that Germany has not yet had time to learn the lessons of cheap production, and her engineers have preferred to continue on the same general lines as before the war, merely bringing their chassis up-to-date in comparison with French, English and Italian makes.

The three companies best known on the world's market are Mercedes, Benz and Opel, all of which are purely automobile concerns, unconnected with other industries. Some of the others, although not so well known abroad, are linked up with very powerful combinations. N. A. G. forms a branch of the A. E. G. (German General Electric Co.), which in turn is allied in a certain measure with the American General Electric. The Protos Co. is a branch of the Siemens Electric concern, one of the biggest manufacturing and industrial organizations in Germany. The Dinos car is in the hands of Hugo Stinnes, probably the biggest manipulator of capital in Europe. Krupp, of gun fame, is also interested in automobile construction, but up to the present the factory has confined its attention to trucks and scooters.

While capable of competing on nearly all foreign markets, with the exception of France, where there is a prohibitive duty against former enemy countries, Germany is doubly protected in her own territory. Not only does the exchange rate make it impossible to import cars into Germany, but it is necessary at the present time to obtain a Government permit to import, and this is not readily given. This state of affairs applies not only to automobiles, but to tires and all accessories. There is an opportunity, however, for American capital to interest itself in the German industry. This has been done by Goodrich, who has secured 50 per cent of the shares of the Continental Tire & Rubber Company of Hanover. Packard has also just bought the Ventzky automobile factory at Graudenz (now named Grudziacz), in West Poland, formerly Prussian territory. It is reported, although no confirmation of this has been obtained, that the Ford Motor Co. has secured a controlling interest in the Hansa-Lloyd Company. Among accessory firms, Klaxon and Zenith manufacture in Germany.

#### Show Statistics

Forty-six passenger car manufacturers are represented at the Berlin show, these firms producing 90 models. Twenty factories build one type only; 15 produce 2 models, 5 have 3 models, 5 have 4 models, and one firm produces 5 different types. About one dozen of these firms are interested also in automobile trucks. The 90 models represented at the show can be divided as follows as regards horsepower:

- 5 models with engines of about 14 hp.
- 3 models with engines of about 15 hp.
- 11 models with engines of about 18 hp.
- 13 models with engines of about 24 hp.
- 4 models with engines of about 25 hp.
- 18 models with engines of about 30 hp.
- 3 models with engines of about 40 hp.
- 13 models with engines of about 45 hp.
- 3 models with engines of about 50 hp.
- 7 models with engines of about 55 hp.
- 4 models with engines of about 75 hp. and more.

The bore-stroke ratios and the engine speed are given in the following table, which indicates the minimum and the maximum:

General view of the recent German automobile show

Brake hp.	Bore-stroke-ratio	R.p.m.
14	1.1 -1.5	1800-2400
15	1.3 -1.55	1600-2500
18	1.25-1.8	1800-2600
24	1.25-1.8	1500-2600
26	1.3 -1.9	1400-2200
30	1.35-2.1	1400-2200
40	1.35-1.7	1600-2200
45	1.3 -1.7	1400-2000
50	1.3 -1.6	1400-2000
55	1.4 -1.45	1400-2200
75	1.1 -1.5	1400-1600

The four-cylinder engine is used in 80 per cent of German automobiles. Six-cylinder engines represent 16.6 per cent, eight-cylinders are 1.13 per cent, and twins and singles are each 1.13 per cent. Germany has not been carried away with the multi-cylinder idea, for there is only one eight-cylinder in the show, this being the Apollo V-type. There is also only one single-cylinder, a two-stroke air-cooled used in a cyclecar.

Vertical cylinders are used on 96.6 per cent of the engines; the W-type is used on the Rumpler six-cylinder, and represents 1.13 per cent of the whole; the V-type is also in the proportion of 1.13 per cent, as applied to the Apollo eight, and the horizontal opposed is 1.13 per cent.

Four-cylinder engines are in one casting in 83.2 per cent of the models; and pairs 16.8 per cent. For six-cylinder engines block casting is found on 33.3 per cent, pairs in 40 per cent, and in threes on 26.7 per cent. In the great majority of cases cylinders are grey iron casting. Mercedes is using steel cylinders for all poppet valve models. There is an increased number of aluminum cylinders with steel liners, most of these having cylinders and crankcase in one casting, detachable heads and overhead valves. Examples are Dinos, Audi, B. M. W., Swave, and Horch. Detachable heads represent only 11 per cent of the whole, while aluminum pistons are used on 42.2 per cent of all models.

#### Head Type Predominates

The L-head engine is at the top of the list with 67.7 per cent, followed by the overhead valve type with 21.1 per cent. L-head engines with inclined valves are 3.3 per cent.

The novel Rumpler car with powerplant aft. Note the appearance of the streamline body

The Knight engine is used by Mercedes, the proportion being 2.2 per cent. There are no other substitutes for the poppet valve. One valve in the head and one operated from below is found on 4.4 per cent of the cars.

On four-cylinder engines the crankshaft bearings are as follows: 2 plain bearings, 5.5 per cent; 3 plain, 76.4 per cent; 4 plain, 4.4 per cent (Dinos car); 2 ball bearings, 6.9 per cent; 3 ball bearings, 2.7 per cent; 4 ball bearings, 1.3 per cent; 5 ball bearings, 2.7 per cent. On six-cylinder engines the proportions are 2 plain bearings, 6.7 per cent; 3 plain, 6.7 per cent; 4 plain, 66.6 per cent; 7 plain, 20 per cent. Ball bearing shafts are not used for six-cylinder engines. The front end drive is by spur pinions on 27.7 per cent of the engines; spiral bevels are used on 21.1 per cent, and chain drive on 43.3 per cent. Bevel gear drive for overhead camshaft is used on 7.9 per cent of the engines.

Cooling is about equally divided between thermo-syphon and pump circulation, the former representing 47.7 per cent and the latter 48.8 per cent. Air cooling represents 3.5 per cent. Fan designs are as follows:

Aluminum	Sheet Steel
2 blade 14.9 per cent	2 blade 14.6 per cent
3 blade 33.3 per cent	3 blade 18.4 per cent
4 blade 11.4 per cent	4 blade 4.8 per cent
6 blade 2.4 per cent	Flywheel-fan 4.8 per cent

Radiator cores are 83.9 per cent tubular and 16.1 per cent honeycomb type. Pointed radiators are found on 92.2 per cent of the cars, half round on 2.3 per cent, and flat on 5.5 per cent. Materials used for the radiator shell are brass, 93.1 per cent; German silver, 2.2 per cent; copper, 3.4 per cent, and aluminum, 1.2 per cent.

The full pressure lubricating system holds the field with 74.4 per cent, combined splash and pressure is 17.7 per cent, splash system 3.5 per cent, and Bosch oiling system 4.4 per cent. Gear type oil pumps are 63.9 per cent of the whole; eccentric pumps, 16.3 per cent; plunger pumps, 19.8 per cent.

In the carburetor field Zenith has a proportion of 38.8 per cent; Pallas, 31.1 per cent; other makes, 15.7 per cent, and car makers' own carburetors are 14.4 per cent. Carburetor control is 1.2 per cent by hand only, 8.7 per cent by accelerator pedal only, and 90 per cent with both. The gasoline tank is at the rear on 78.3 per cent of the cars, on the dash on 21.6 per cent, and below the driver's seat on 1.1 per cent. Fuel feeds are 11.1 exhaust pressure, 22.3 air pressure, 45.5 vacuum, 21.1 gravity.

#### Ignition Systems

Ignition by a single magneto is 90.3 per cent; double ignition is 6.6 per cent, and battery-dynamo 2.2 per cent. Bosch equips 80 per cent of the cars with magnetos. Spark

control is by hand lever on 72.2 per cent of the cars, fixed on 8.8 per cent, and automatic on 20 per cent. N. A. G. has a combination of hand lever and automatic control. Electric lighting is used on 94.5 per cent of the cars, practically all of these being Bosch, and acetylene on 5.5 per cent. Electric starting is 67.7 per cent, and cars without starter 32.3 per cent. Battery boxes are mounted on the running board on 60.1 per cent of the cars, inside the frame on 30.1 per cent, and below driver's seat on 9.4 per cent.

The clutch systems are 48.2 per cent leather cone; Ferodo cone, 16.6 per cent; double cone, 4.4 per cent; metal cone, 5.5 per cent; steel disks, 14.4 per cent; brass and steel disks, 7.7 per cent; dry disks, 3.3 per cent; three plate, 4.4 per cent; extension clutches, 1.1 per cent, and reversed cone, 4.4 per cent. A clutch stop is fitted on 58.8 per cent of the cars.

Unit construction of engine and transmission is 21.1 per cent; engine and transmission separate is 75.6 per cent, and transmission on rear axle 1.1 per cent. Rumpler has engine and transmission forming a block mounted at the rear, the percentage being 2.2. Four speeds ahead represent 83.4 per cent; three-speed transmissions, 14.4 per cent; two-speeds, 1.1 per cent, and a single-speed, 1.1 per cent. This latter is the Maybach so-called transmission-less car.

Spiral bevel gears for the final drive are 39 per cent; straight bevels, 58.6 per cent, and worm gear, 2.4 per cent. Differentials are nearly all bevel type, only four cars having spur gear differentials.

Wood wheels hold the premier position with 40 per cent; wire wheels, 27.7 per cent; steel disk wheels, 11.1 per cent; steel spoke wheels, 18 per cent. Detachable wheels are 43.2 per cent; detachable rims, 53.3 per cent; fixed wheels and rims are 4.5 per cent. All rims are clincher bead

Rear end of Rumpler chassis. The W-type engine, gearbox and differential housing are built in one unit, most of the weight being sprung. The springs are inside the chassis frame

type. Front axles are 37.5 per cent open jaw type and 62.5 per cent closed jaw.

Front springs are 91.2 per cent half-elliptic, 3.3 per cent cantilever (Rumpler car), 3.3 per cent transverse, and 2.2 per cent quarter-elliptic. At the rear 62.1 per cent are half-elliptic, 24.4 per cent cantilever, 6.6 per cent three-quarter-elliptic, 2.2 per cent transverse, 1.1 per cent quarter-elliptic, 1.1 per cent spiral, and 2.5 per cent other systems.

Right-hand steering and right-hand control represents 89.4 per cent; left-hand steering with center control is 6.7 per cent, and right-hand steering with center control 3.6 per cent. Steering-gear is worm and sector on 43.3 per cent; screw and nut on 55.5 per cent, and other types 1.1 per cent.

Front wheel brakes have only just made their appearance in Germany, being found only on 2.2 per cent of the cars. Foot brake on the transmission is 91.2 per cent and on rear wheels 8.8 per cent; hand operated brake on rear wheels is 97.8 per cent. Fifty-seven per cent of transmission brakes are external and 33 per cent internal. Only 3.6 per cent of these are water cooled. The percentage of external rear brakes is 4.4. Brake equalizers are 82.2 per cent by balance lever, 14.4 per cent by cable and 3.3 per cent by bevel gears.

The following chassis weights, without fuel and oil, show wide ranges of difference. In each case the lightest and the heaviest chassis has been taken.

Engine hp.	14	15	18	24	30	45	55	75 and more
Weight in	840	925	1150	1655	1985	2115	2645	about 3970
pounds:	1100	1230	1870	2095	2910	3085	3750	

### Rumpler Design Radical

Two cars stand out as distinctly different from the others. They are the Rumpler and the Maybach. Before becoming an airplane manufacturer Rumpler was chief designer in some of the leading German automobile factories, and has tackled the problem of automobile production from the double standpoint of the automobile engineer and the aviation expert. He has sought to eliminate unsprung weight and by the general arrangement of his chassis to obtain the best stream-line form. While other makers have sought to reduce head resistance by modifications of existing types of chassis, Rumpler has laid his whole car out with stream lining in view. These cars attracted immense attention and generally favorable comment, despite their unusual appearance. Rumpler puts his engine and transmission at the rear, inside a boat-type chassis. He has adopted a six-cylinder W-type engine with all-aluminum cylinder and overhead valves, but any type of four-cylinder engine can be used equally well.

A clutch and gearbox form a unit with the engine, and the final drive is through a common differential to the two road wheels, there being two driving and two driven pinions, of different size, but with the same ratios. On the inner end of each of the two axle housings is a bronze semi-circular guide to allow of the rise and fall of the axle as the wheel passes over obstacles on the road. There is a stay from each extremity of the axle housing to a bronze bushed trunnion bearing on a rear extension of the differential housing. With this design, which Rumpler declares to be fully covered by patents, the only unsprung weight is the wheel, the driveshaft and a portion of the spring.

Cantilever springs are used front and rear, the front springs being entirely inside the boat type chassis, and the rear springs having about half their length inside the

The Maybach six-cylinder "transmissionless" car with salon body was the most expensive car at the Berlin show

frame. Steering is at the front, with the axle and steering control lever passing through openings in the frame. This design gives an exceptionally low center of gravity. Even the spare wheels are carried inside the frame. Each one is placed flat on a small bogey, which is pushed through openings in the frame on to rails flush with the bottom flange of the frame members. A perfectly stream-lined body is mounted on this chassis. The underpan is just as efficient as the upper works, and no provision is made for external projections which would spoil the effect sought. It is impossible to hang a trunk or a bag on the outside of the car. Fenders, door steps, headlights and windscreen are all treated from an aviation standpoint. The rear seat is practically in the center of gravity and all passengers are carried within the wheelbase. In addition to building this car himself, Rumpler is arranging to grant licenses for its production by other firms.

### The Maybach

Maybach has produced what is termed a transmissionless car. A six-cylinder engine, built to the same designs as the Dutch Spyker, and having a bore and stroke of 95 by 135 mm., is mounted in the usual type of chassis and drives direct by propeller shaft to a bevel type rear axle. The starting motor is sufficiently powerful to move the entire car on the level until the engine begins to fire, and this is the usual method of starting away, all the driving being done on the throttle. A planetary emergency gear is fitted, however, as well as a clutch, although it is claimed that these have only to be used for exceptionally steep hills, or when starting on hills. The rear axle is an all-aluminum structure, and the conical housing carrying the driving pinion is also aluminum. Large diameter brakes are fitted on front and rear wheels, with an adjustment for the application of the rear brakes ahead of those on the front wheels.

Brennabor is the only maker who appears to have laid out his chassis with cheap production in view. The car is a four-passenger with four-cylinder engine, 70 by 102 mm., cylinders and crankcase in one casting, two bearing crankshaft, overhead valves with push rods, three-speed transmission forming a unit with the engine, a generator-battery type of ignition, center control with left-hand steering, and cantilever suspension. This is the European type four and five-passenger economical light car which by reason of low exchange can come into direct competition on all open markets with similar productions of British, French and Italian construction.

Considered as a whole, German manufacturers have specialized in a good quality, medium price car. There

The novel double quarter-elliptic spring construction employed on the Horch chassis is said to prevent rolling and make for easy riding

has been no attempt to compete with the cheapest American types, and the Germans have avoided the French mistake of two years ago of producing mechanical masterpieces irrespective of price. Compared with France, they have made no progress on brakes and have not seriously tackled the problem of four wheel brakes. There are three or four cars in the show with brakes on all the wheels, but it is obvious from an examination that they have been produced without any important amount of practical experience behind these braking systems.

Cantilever springs in Germany are looked upon as a novelty, whereas in most other European countries this system of suspension is on the wane, for it has been found defective for really fast cars. One of the few interesting and new types of suspension is that on the Horch car. On this model use is made of double quarter-elliptics, one of the springs being ahead of the axle, with its thick end forward, and the other to the rear of the axle, with its thick end at the extremity of the frame. The two thin ends are attached by an eye bolt to a sleeve mounted with a bronze bushing on the axle housing. The advantages claimed for this type of spring are flexibility equal to that of the cantilever, reduced weight, and an absence of rolling at high speeds.

#### Central Drive Favored

German engineers are not at all partisans of the Hotchkiss drive, not a single car on this principle being found in the show. There is an increasing number of cars with central drive, the forward end of the propeller shaft housing either being forked or forming a sphere. This latter is a type of drive which has become particularly popular in France and Italy. Invariably, however, when this type of drive is adopted, stays are used from the extremities of the axle housing to a point on the front end of the propeller shaft housing. Benz continues to make use of tubular radius rods, although these went out of existence in other European countries several years ago. One of the exceptions to the German school is the Horch, in which a T-shape combined axle and propeller shaft housing is used, this being formed of two stampings welded together, the drive being through the spherical end of the propeller shaft housing. This exception is explained by the fact that the engineer had long experience with the Fiat Company in Italy, and has been influenced by Italian practice. On this car the differential is contained in an oil tight housing inside the axle housing, not only eliminating all possibility of leakage along the drive shafts but, it is

claimed, reducing noise by reason of this double housing.

Since pre-war days there has been a wonderful cleaning up of the details of engine and chassis. External oil pipes, straggling ignition leads, external manifolds, visible bolt heads, etc., have been removed, some of the best German constructions now approaching the clean lines for which Italian chassis are famous.

#### Steel Cylinder Liners Popular

Overhead valve engines and aluminum cylinders with steel liners are not in a majority, but it is evident that German engineers are working along these lines. There are some really good examples in this connection. A good example is the powerplant built in Munich by the Bayerische Motoren Werke for car assemblers. This firm made a reputation during the war on aviation engines, and since then has specialized on automobile engines. Its latest type is designated a compound motor and has cylinders and base chamber in one aluminum casting, steel liners for the cylinders, a detachable cast iron head, and four valves per cylinder inclined in the head. This being a sporting type engine, double ignition is fitted, with two magnetos driven off a cross shaft at the front. As the illustration shows, very clean lines have been obtained. A reserve oil tank is cast in the housing around the flywheel. This engine being a high efficiency type, 95 by 170 mm., with five bearing balanced crankshaft, it is intended to put it on the market with a two-speed transmission.

Horch, although exhibiting two L-head types with cast iron cylinders on an aluminum crankcase, having unit transmission, has two new all-aluminum engines ready, one with four and the other with six cylinders. These are steel lined cylinders with overhead camshaft and concealed vertical drive. Swave is another case of all-aluminum unit construction, with a detachable cast iron head and inclined valves in the head, the general lines of which can be gathered from the illustrations.

N. A. G. has a cheaper production job with detachable head, cast iron cylinders on an aluminum base chamber, and overhead valves with push rods concealed in the cylinder casting. The design is not costly and the general layout equal to that of the best to be found elsewhere. One of the features of this chassis is the direct mounting of the separate gearbox on a stiffened mud pan, instead of on the main or sub-frame. All-aluminum engines have even made their appearance for trucks, the best example being the Hille, produced in Dresden. This has aluminum cast cylinders with detachable cast iron head and overhead valves. Generator-battery ignition has not made its presence felt in Germany for, with the exception of the Dinos, controlled by Hugo Stinnes, and one or two others, the magneto is used everywhere. The reason for this is that Bosch dominates the German automobile industry, and so long as that firm adheres to the magneto, automobile manufacturers will doubtless follow suit. Bosch has produced a combined generator and magneto, but this is not a generator-battery ignition as exemplified in the Delco, but a combination of the two units which facilitates mounting. A German branch of the Delco exists, but no car was seen in Germany with Delco equipment.

#### Body Design

The open body dominates in Germany, with the sedan following a long way in the rear. German body designers have developed distinctively Teutonic lines. Invariably radiators are pointed, body sides are hollow, the stern generally is brought to a point, and the folding top is always concealed. All bodies are bright colored. Very frequently the top of the hood and a deep line running round the body and taking in the top housing is in a dark color with the rest of the body in a lighter tint of the same

color. There are infinite variations on these general lines, but there are no exceptions to this general type. There is a great love for beaten metal radiator shells and even engine hoods, many of these imitating beaten bronze. Fantastic designs in paneling are very common, and it would almost seem as if the body designers had sought to make automobiles which would attract attention by reason of their eccentricity. As an example there is an all-aluminum body with etched designs on it. In itself the typical German line is not displeasing, but when it is accentuated by strong contrast in panels, by abrupt angles in the fenders, and by startling colors, the result is often hideous—at any rate to any one trained to body lines as developed in all other countries of the world.

For passenger cars only clincher bead fabric tires are used. The Continental detachable rim is very extensively used, being seen more often than the detachable wheel. Steel disk wheels are not much in favor, but the steel spoke wheel is growing in popularity. Aluminum disk wheels have appeared, but are not yet employed to any great extent.

By reason of American participation in the Continental Rubber Company, giant straight side cord tires have made their appearance on the German market, and are being used for trucks and passenger-carrying sight-seeing automobiles. This is an important development for Germany, which during the war was totally deprived of rubber and a year ago had not seen a giant pneumatic tire or had any experience with straight side tires. The new tire is being used on three to five-ton trucks, both as singles and as duals. The combinations most generally seen were 40 by 8 in. dual on four and five-ton trucks and 42 by 9 in. single on three-ton trucks and sight-seeing automobiles.

### Truck Industry

The German truck industry has been left free to develop on commercial lines since the war, for the army subsidy, with the military restrictions which were formerly imposed, has been abolished. As a consequence considerable improvements have been made in design, and in particular an effort has been made to reduce weight. For truck engines there is a very extensive use of overhead valves, with the camshaft in the base chamber, and with or without detachable head. The most popular type of final drive is double reduction.

There was nothing in the German show to indicate that agricultural tractors have been adopted. It is known that Mercedes and Benz have produced this type of machine, but without any great amount of success. Speaking generally, the tractor has still to be developed in Germany.

Germany's speedway is jointly owned by the German Association of Automobile Manufacturers and the German (formerly the Imperial) Automobile Club. Its construction was begun in 1913, but all work was stopped during the war, and it was only by an effort that the track was finished in time for the first races to be held on the day the German automobile show opened.

The track has a very choice location at Grunewald, on the western end of the city of Berlin, about six or seven miles from the heart of the city, and is conveniently

reached by subway, railway and surface cars. The main entrance to the track is but a short distance from the Kaiserdamm Exhibition Hall, belonging to the German Association of Automobile Manufacturers. By reason of its location it should be an easy matter to make this track a paying proposition.

The speedway consists of two parallel tracks, with a loop at each end, running in a dead straight line through Government-owned forest land. The length of the track is 12.4 miles. On the straightaway the average width of the tracks is 33 feet, this width being increased to 70 feet on the loops. The space between the two tracks is about 25 feet. Banking on the loops is very slight, and the outer protecting wall is quite insufficient to arrest a car which has got out of control. On the straightaways there are no safety zones, and the trees which line the track constitute an additional danger in case of a burst tire or breakage of the steering gear. In its present condition the track is neither safe nor of such a nature that records can be broken on it. On the first practice day a car went over the top of the banking and during the first day's racing there were accidents of a minor nature. Material used for the surface is tar macadam. This doubtless will be satisfactory on the straightaway, but it will not stand up on the loops.

Above—The Swave aluminum overhead valve engine, a good example of modern German construction. Below—The all aluminum four-valve B. M. W. unit powerplant resembles some American powerplants in external appearance

# Longer Wheelbase and Larger Engine in New Haynes

New model "75" has 132 in. wheelbase and 299 cu. in. engine with block-cast cylinders, inclined valves, chain distribution, three-piece separate head, aluminum crankcase and hollow shaft lubrication. Pump circulates water through radiator when thermostatic valve is closed.

By J. Edward Schipper

**T**HE 1922 Haynes is a newly designed car with a 132-in. wheelbase and incorporates an entirely new and more powerful engine than any of the preceding sixes. It is known as model 75. The smaller six, known as the "55," with 121-in. wheelbase, is continued.

Production is just starting on the new model, including the new engine with which it is equipped. The Haynes factory manufactures a very high percentage of its own parts. It has its own forge shop and extensive machine shop equipment so that the new engine, as well as the majority of parts which enter the car, are

produced in the one plant. The "75" chassis is a refinement of the larger type which Haynes put out last year equipped with the same engine which is now in the "55."

The new powerplant is an L-head, six-cylinder type, developing 75 b. hp. at 2600 r.p.m. It is of conventional L-head construction incorporating all of the features which characterize the later units of this type, such as inclined valves, extreme rigidity in crankshaft and crankcase construction and accessibility, particularly in the valve mechanism. One of the new features is an installation of the Link-Belt chain drive at the front

Lateral sectional view of the new Haynes  $3\frac{1}{2} \times 5\frac{1}{8}$  in., six-cylinder engine.

end with the new automatic spring take-up recently brought out by this concern in connection with a double-sided chain having sprocket contact on both sides.

### How Operated

The engine is block-cast with  $3\frac{1}{2}$  by  $5\frac{3}{16}$ -in. cylinders, giving a displacement of 299 cu. in. The bore of the new engine is the same as that used in model 47, but the stroke is  $\frac{3}{16}$  longer. The valves, which were formerly on the right, are now on the left side of the block and are inclined at an angle of 4 deg. toward the center of the cylinder. This results in a combustion chamber shape which can be readily machined out. The cylinders and water jacket are cast in one piece and the head is detachable. The head is made in three sections to allow for expansion without warping. In machining the cylinder heads, they are located from the inner surface so that the clearance in all cylinders is the same, giving uniformity in compression pressure.

The crankcase is an aluminum casting. The lower half of the case, or oil pan, is also an aluminum casting instead of the conventional stamping. The main bearings are supported in the crankcase, and six through bolts from the bearing caps pass through the case to the cylinder block, thus tying the units together and relieving the case of certain stresses which would otherwise be imposed.

The cast iron pistons are  $4\frac{1}{2}$  in. in length and have three rings all located above the piston pin. The piston pin is  $1\frac{1}{8}$  in. in diameter and is clamped in the piston boss by a tapered lock screw which is threaded into the bottom of the boss and is held in place by a steel locking spring which replaces the cotter pin ordinarily used for this purpose. The bearing is in the upper end of the rod, which carries a bronze bushing. The piston is

Plan view of oil piping used in the new Haynes

grooved below the bottom ring and is drilled around the periphery with twenty  $\frac{5}{32}$  in. holes. There are two grooves at the bottom of the skirt which act as oil scrapers.

The connecting rods are of H-section flared at the lower ends. They are 11 in. in length, center to center. The big end bearings are  $2\frac{1}{4}$  in. diameter by  $2\frac{1}{4}$  in. in length. The crankshaft is carried in four bearings. It has a nominal diameter of  $2\frac{1}{4}$  in. The lengths of the four crankshaft bearings from front to rear are,  $2\frac{1}{4}$ ,  $2\frac{1}{4}$  and  $3\frac{1}{4}$  in.

The front end drive is a triangular layout with the addition of the spring tension idler, which is placed against the back of the chain. Some of the links in the Link-Belt liner type chain are reversed to engage with this idler sprocket. The entire auxiliary drive is taken off the timing chain. The auxiliary shaft carries the fan pulley at the front end forward of the timing chain case and the water pump and generator, which incorporates the distributor, at its rear end on the other side of the timing chain case. The oil pump is driven from the camshaft. Flexibility in the drive between the water pump and the generator is secured by the insertion of a three-disk flexible coupling. By placing the distributor on the rear end of the generator, near the center of length of the engine, it is possible to minimize the length of high tension wires from distributor to plugs.

The valve followers are mushroom type and these, together with the tappet guides, are mounted in assemblies of four, held in position by two cap screws and pilot tubes for proper alignment. This gives an accessible layout for, by removing the cap screws, the entire assembly can be lifted from the engine. The engine fires 1-4-2-6-3-5, and the valve timing is such that the exhaust opens 50 deg. before lower center and closes 6 deg. after upper center. The intake opens at 8 deg. after upper center and closes 44 deg. after lower center.

The camshaft is carried in four bearings. The valves are  $1\frac{3}{4}$  in. clear diameter and have  $\frac{11}{32}$ -in. lift. The exhaust valves are tulip-shape and of different composition than the intake valves, being made of an alloy which has greater heat resisting characteristics.

A pressure feed lubricating system with a maximum of 40 lb. per sq. in. pressure is used. At a running speed of 25 miles per hr. the pressure on the oil varies from 20 to 25 lb. The oil is circulated by a gear pump driven through a short vertical shaft from the rear end of the camshaft. The pump is mounted outside and on the bottom of the upper half of the crankcase. The lower pan has an external recess into which the oil pump is set. It can be removed without disturbing any of the other parts of the engine. It delivers into the main oil line inside the crankcase and leads, from this line, conduct the oil under pressure to the camshaft bearings and to an annular groove in each of the crankshaft

Transverse sectional view of new Haynes engine, showing inclined valves

The new Haynes six, showing details of the vaporizing system, water pump and thermostat, valve tappet assembly and chain distribution with spiral-spring-controlled idler sprocket

main bearings. The crankshaft is drilled from each main bearing to the adjacent crankpin, the holes lining up with the oil groove, so that the connecting rod bearings are also pressure oiled.

There is a lead from the front crankshaft bearing to the timing chain idler sprocket and to the accessory shaft bearing. The idler sprocket shaft is hollow, and the oil works its way through the shaft to the sprocket, and through a hole in the sprocket on to the chain. A relief valve is fitted to prevent excess pressure at high speeds. The pistons, piston pins and valve mechanism are lubricated by oil spray thrown from the connecting rods.

The fuel is fed by vacuum from a gasoline tank, mounted on the rear of the chain to a  $1\frac{1}{8}$ -in. vertical Stromberg carbureter. A number of innovations have been made in the manifolding to facilitate vaporization of the fuel. The exhaust manifold is led forward on this powerplant and cooling fins placed upon it at its forward end, where it bends downward. The center of the intake manifold is partially exhaust jacketed. Some of the exhaust gas passes through this jacket and enters the exhaust pipe at a point near the rear end of the engine. A damper, by means of which can be controlled, is provided the amount of exhaust gases which enter this jacket. In addition, all of the air which enters the carbureter is pre-heated by means of a stove clamped around the exhaust pipe at a point just below its connection with the manifold. There is a sleeve adjustment on this air intake which permits of admitting cold air at this point when desired.

The electrical equipment comprises a Leece-Neville generator and starter with a Kingston distributor for ignition and a Bendix gear for flywheel engagement. The starter is controlled by a magnetically operated switch which is controlled by contacts on the ignition

switch lever. Both the generator and starting motor are located on the right side of the engine away from the steering gear. The carbureter and manifolding are on the left side of the engine.

A Rayfield thermostatic control is employed on the water circulation which is by centrifugal pump. The thermostat is mounted on the water outlet above the cylinder block. The thermostat is so arranged that it permits circulation through the entire system at 140 to 150 deg. Fahr. When the engine is cold the water is circulated through the radiator and as it warms up only enough water is by-passed through the jacket to keep the engine at the desired working temperature. This differs from the practice of circulating the water through the jacket and leaving it stationary in the radiator, which is apt to cause freezing in cold weather. In this system, some thermo-syphon circulation takes place around the cylinder block before the radiator comes into action.

A 12-in. Borg & Beck clutch transmits the power to a three-speed selective gearbox manufactured at the Haynes plant. The gearbox is of conventional construction, but incorporates an air pump for the tires. The mounting of the shifter lever is so arranged that a coil spring forces a compressed felt packing against the bottom of the lever. This prevents any throwing of oil from the gearset up through the shifter lever joints into the driver's compartment.

The drive to the three-quarter floating rear axle, which is also a Haynes product, is through two universal joints. The axle is mounted on Gurney ball bearings and is equipped with spiral bevel gears. The drive is through the springs, but torque and braking reaction is taken by a torque arm, which has been added in this model. The external and internal brake has also been adopted in place of the side-by-side internal brakes

formerly employed. The brakes are 16 in. in diameter by 2½ in. in width. The tires are 34 by 4½-in. cords all around. The front axle is a conventional Elliot type and steering is by Jacox gear.

All the body types are mounted on the same 132-in. wheelbase chassis. The bodies are all made of aluminum

The new external and internal brakes, which take the place of the pair of internal, side-by-side brakes formerly used

formed over a wooden frame. The lamp equipment comprises exterior side cowl lights of a design identical with that of the headlamps. A feature in the control system is that the starting and lighting is operated from the instrument board.

The touring car, "tourister" and "speedster" model, are upholstered in genuine leather applied in front plaits over the seat springs. The brougham, sedan and

Sectional view of the gearset used in the new model 75 Haynes

suburban models are equipped with mahogany fittings, vanity cases, smoking cases, etc. There is an indirect dome light and a car heater on the closed cars. Prices on the model 75 are as follows: Seven passenger touring, \$2485; four-passenger "tourister," \$2485; two-passenger special "speedster," \$2685; five-passenger brougham, \$3185; seven-passenger sedan, \$3485; seven-passenger "suburban," \$3485.

## From Passenger Coach to Truck

**A** FEATURE of the summer touring season in England and Scotland has been the big extension of public automobile coach services. Until a few weeks since these services had the summer touring season much to themselves, for their fares relatively were lower than the normal rail fares and the public were able to explore scenic beauties away from the railroad tracks. The competition had the effect of forcing down rail fares and leveling up competition, until now there is evidence of a shrinkage in the paying capacity of a number of auto-coach ventures.

This fact, coupled with the approaching end of the tourist season, has led the coach interests to devise means and routes to find work for the vehicles as carriers of goods. But again there are signs that the railroad interests are likely to reduce rates, even to the extent of starting a cut-rate war. Such a war is less likely to succeed now because, within a short time, British railroads will be working on the group system, as a measure of economy imposed by the Government through the Ministry of Transport. It follows that if the railroads cannot cut rates among themselves to compete for local traffic when the localities are served by two or more rival companies, they are unlikely to cut rates against automobile traffic to the limit possible if each company were fighting its own battle against all comers. What is more likely, however, is that the railroads themselves will start automobile service ostensibly for collecting and delivering rail borne traffic, the cost being included in a through terminal rate. At present much commercial vehicle traffic is really rail consigned.

However, the interests concerned are alive to the situation and scores of automobiles are being prepared for a

winter's use as merchandise carriers. The tactics of the railroad interests also are being adopted as regards organization and co-operation, through rates and standard changes and clearing house facilities, which include provision for insuring full or at least a paying return journey. Altogether things look like being lively in traffic affairs during the next few months, provided there is an improvement in trade. It may be added that the trend toward using smaller capacity and air-tired coaches offers a better prospect for the automobile carriers than would have been the case last year.

## New York Electrical Show

**T**HE New York Electrical Show, which closed Oct. 8, had on display a number of electric trucks, and the manufacturers exhibiting them reported gratifying results. There was not an enormous number of sales made at the show, but the various exhibitors said they had entertained many prospective buyers and felt that the results would be felt in due time. The Walter Motor Truck Corporation of New York made the largest number of sales during the show, disposing of twelve trucks. The locking differential and other new features attracted buyers who said they were users of the gasoline truck but were anxious to give the electrics a trial.

The Commercial Truck Co. of Philadelphia made two sales, and the Landsden Co. of Danbury, Conn., made one.

Next year's exhibit will be held in the Grand Central Palace, it was announced.

# The Testing of Motor Fuels

## Part II\*

In Part I of this manual the need for careful tests of motor fuel and interpretation of results of tests were covered. Part II describes in detail the apparatus required and the methods to be followed in the tests.

### 1—Specific Gravity

**T**HE apparatus for determining the gravity of gasoline may be a Westphal balance (Fig. 7) or an accurate hydrometer of the long stem type (Fig. 10) graduated from 0.700 to 0.800 at 60 deg. Fahr. (15.5 deg. C.). If benzol mixtures are met with, a hydrometer having a scale graduated from 0.800 to 0.900 is also necessary.

Care should be taken that the gravity determination is made at 60 deg. Fahr. (15.5 deg. C.).

### 2—Distillation Range\*\*

The equipment required consists of the layout shown in Fig. 8 made up of

Standard 100 cc. Engler Flask for oil distillation made of Pyrex glass to dimensions given in Fig. 9.

Suitable support with  $\frac{1}{8}$  in. to  $\frac{3}{16}$  in. thickness of asbestos 6 in. square having an opening  $1\frac{1}{4}$  in. in diameter. Only this limited portion of flask is to be heated. Wire gauze must not be used.

Thermometer of selected enamel backed tubing, as described below under Apparatus Specification.

Condenser. The dimensions and construction to conform to standards as described below under Apparatus Specification.

Graduate. 100 cc. glass graduated cylinder. See Apparatus Specification.

Source of heat may be a gas burner, alcohol lamp, or electric heater.

### Procedure and Details of Manipulation in Conduction of Distillation

1—The condenser trough is filled with water containing a liberal portion of cracked ice. The temperature should not be lower than 32 deg. Fahr. nor above 40 deg. Fahr. (0 deg.-5 deg. C.). The condenser tube is swabbed to remove any liquid remaining from a previous distillation.

2—One hundred c.c. of gasoline is measured, at a temperature of 60 deg. Fahr. (15.5 deg. C.) into a clean, dry Engler flask from a 100-c.c. graduate. The same graduate is used as a receiver for distillates without any drying. This procedure eliminates errors from an apparent distillation loss due to the impossibility of draining the gasoline entirely from the graduate.

3—The same graduate is placed under the lower end of the condenser tube so that the latter extends downward below the top of the graduate at least 1 inch. If the room temperature be above 80 deg. Fahr. (27 deg. C.), the receiving graduate shall be placed in a bath maintained at a temperature not less

than 65 deg. Fahr. (18 deg. C.) nor more than 75 deg. Fahr. (24 deg. C.). The condenser tube shall be so shaped and bent that the tip can touch the wall of the graduate on the side adjacent to the condenser box. This detail permits distillates to run down the side of the graduate and avoids disturbance of the meniscus caused by the falling of drops. The top of the graduate is covered, preferably by several thicknesses of filter paper or blotting paper, the condenser tube passing through a snugly fitting opening. This minimizes losses due to circulation of air through the graduate and also excludes any water that may run down the outside of the condenser tube on account of condensation on the ice-cooled condenser box.

4—A boiling stone, a piece of unglazed porcelain or other similar material not exceeding one-fourth inch in any dimension, is dropped into the gasoline in the Engler flask. The thermometer is equipped with a well-fitted cork and its bulb covered with a thin film of absorbent cotton (preferably the long-fibered variety used for surgical dressing). The quantity of cotton used shall be not less than 0.005 nor more than 0.010 gram (5 to 10 milligrams). The thermometer is fitted into the flask with the top of the bulb just below the lower level of the side neck opening. The flask is connected with the condenser tube by means of a well-fitted cork or stuffing box. The vapor tube must extend at least  $1\frac{1}{4}$  inches into the condenser tube.

5—Heat must be so applied that the first drop of the gasoline falls from the end of the condenser tube in not less than five nor more than ten minutes. The initial boiling point is the temperature shown by the thermometer when the first drop falls from the end of the condenser tube into the graduate. The amount of heat is then increased so that the distillation proceeds at a rate of from 4 c.c. to 5 c.c. per minute, which is approximately two drops a second. The graduate is moved occasionally in order to permit the operator to ascertain whether the speed of distillation is right as indicated by the rate at which the drops fall. The thermometer is read as each of the selected percentage marks is reached. The maximum boiling point or end point is determined by continuing the heating until the column of mercury reaches a maximum and then starts to recede consistently.

6—Distillation loss is determined as follows: The condenser tube is allowed to drain for at least five minutes after heat is shut off and then a final reading taken of the quantity of distillate collected in the receiving graduate. The distillation flask is removed from the condenser and thoroughly cooled as soon as it can be handled. The condensed residue is poured into a small graduate or graduated test tube and its volume noted. The sum of this volume and the volume collected in the receiving graduate subtracted from 100 c.c. gives the figure for distillation loss.

### 3—Acidity†

The cooled residue from the distillation flask is collected in a test tube and its volume noted. Three volumes of distilled water are then added and the tube is shaken thoroughly. The mixture is allowed to separate and the aqueous layer is removed to a clean test tube by means of a pipette and one drop of a 1 per cent solution of methyl orange in distilled water is added. No pink or red color should be formed.

\*This manual was prepared by the General Motors Research Corporation and edited by T. A. Boyd of the Fuel Section of that organization.

\*\*The apparatus specified and the procedure to be followed in this test is adapted from "Report of Committee on Standardization of Petroleum Specifications." Bulletin 5 of the U. S. Bureau of Mines.

†Method recommended by Committee on Standardization of Petroleum Specifications.

#### 4—Percentage of Unsaturation

The most convenient form of apparatus for use in this test and one which gives sufficient accuracy for commercial work is the ordinary 10 cc. graduated cylinder with ground glass stopper (Fig. 12).

Exactly 5 c.c. of the gasoline is put into the graduated cylinder by adjusting the level so that the bottom of the meniscus is just even with the 5 c.c. mark after the gasoline has been well shaken in the cylinder with the stopper closed and has been allowed to come to rest.

The cylinder and gasoline should then be thoroughly cooled in ice water; after which slightly less than 5 c.c. of sulphuric acid (specific gravity 1.84) is poured into it, care being taken that the acid does not splash onto the surface of the gasoline but runs quietly down the side of the cylinder. After securely replacing the stopper and thoroughly cooling the graduate and contents in ice water, the acid should be brought into more intimate contact with the gasoline, first, by rotating the graduate in a nearly horizontal position. If no appreciable heat develops in this way, the acid may then be thoroughly mixed with the gasoline by a vigorous endwise shaking. This shaking should be continued intermittently for several minutes and between the periods of agitation the graduate should be cooled in ice water to prevent loss of gasoline. After allowing the cylinder to stand for several hours, preferably over night, the absorption is read directly.

#### 5—Content of Gummy Materials (Corrosion Test)

A freshly polished hemispherical dish of spun copper, approximately 3½ in. in diameter is required.

Pour into the dish 100 c.c. of the gasoline to be examined, and place the dish in an opening of an actively boiling steam bath so that the steam comes in contact with the outer surface of the dish up to the level of the gasoline. If a steam bath is not available a 500 or 600 c.c. glass beaker half filled with water will serve the purpose. The water should, of course, not be heated with an open flame, because of the danger of fire from the vaporized gasoline, but either an open steam line or an electric hot plate should be used. Allow the dish to remain on the steam bath until all volatile portions have disappeared. Then note—

1—Whether there is a visible amount of gum deposited in the dish. The weight of this gum may be determined if the empty dish has been accurately weighed at the beginning of the test. The dish should be cooled and thoroughly dried before it is weighed.

2—Whether the bottom of the dish is colored gray or black.

#### 6—Content of Aromatic. Hydrocarbons (Benzol, Etc.)

**Detection of Presence in a Gasoline:** The presence of benzol in a gasoline can usually be determined from the relation between its specific gravity and distillation data, as outlined under the corresponding heads in Interpretation of Results given in Part I. The following method is given for the determination of the amount of benzol in a fuel.

**Determination of the amount of aromatics present—**The method which is given here for the quantitative determination of benzol and similar hydrocarbons in gasoline has been worked out at the General Motors Laboratory. It is based on the reaction between nitric acid and aromatic hydrocarbons to form nitrobenzene (oil of mirbane), nitrotoluene, etc. The nitrating mixture has no action on the paraffin or naphthene hydrocarbons in the cold. The method is fairly rapid and is sufficiently accurate for commercial work. Because of the nature of this process it should not be attempted by anyone unless he has had some experience with chemical reactions. This is because of the very strong and highly corrosive mixture of acids which it is necessary to use, and because the rate of the reaction must be controlled in order to prevent the danger resulting from the development of too much heat.

**Apparatus—**Westphal balance, or accurate hydrometer as above (Figs. 7 and 10); 500 c.c. round bottom flask with long neck (Fig. 14); 500 c.c. separatory funnel with ground glass

Fig. 7—Above: The Westphal Balance used for accurate determination of specific gravity. Fig. 8—Below: Standard Engler distillation apparatus, showing arrangement of flask, condenser, etc.

stopper (Fig. 15); glass filter funnel, about 2 in. in diameter.

**Reagents—**A nitrating mixture composed of acids in the ratio of

150 g. sulphuric acid (sp. gr. 1.84)

100 g. nitric acid (sp. gr. 1.42)

Solution of sodium hydroxide (30 per cent sodium hydroxide in distilled water)

Fused calcium chloride.

**Method—1—**Determine accurately the specific gravity of the fuel at 60 deg. Fahr. If the percentage of unsaturated hydrocarbons as previously determined exceeds 5, the fuel should be cooled in ice water and thoroughly washed with sulphuric acid (sp. gr. 1.84), the acid completely removed by washing with water, with a dilute solution of sodium hydroxide, and with water again, and the resulting gasoline dried with fused calcium chloride before the specific gravity is determined.

**2—**Place about 200 c.c. of the fuel in a 500-c.c. round bottom flask with a long neck. If the percentage of benzol in the blend is over 50, as indicated by its specific gravity and distillation data, it should be diluted with a measured amount of gasoline which is known to contain practically no aromatics and which has previously been thoroughly washed in the cold with sulphuric acid (sp. gr. 1.84) so that the final percentage of benzol is from 30 to 40. The specific gravity of this mixture should be determined and the value used in the calculation of the percentage of benzol in the original fuel as given below. After thoroughly cooling the flask and contents in ice water about 50 c.c. of the nitrating mixture is added to it, being careful to add it in such a way that it does not splash onto the surface of the fuel, but runs down the side of the flask. The flask is closed by a rubber stopper into which is inserted a piece of capillary or small bore glass tubing which extends about a foot above the stopper. After the flask with

its contents has been again cooled in ice water, it is removed and the fuel and nitrating mixture are mixed by a gently endwise shaking. A large amount of heat is generated by the reaction which is thus induced, and care must be taken that the temperature of the nitrating mixture does not rise above 40 deg. C. (104 deg. Fahr.). The temperature of the reacting mixture must be kept low by means of the cooling bath, both to prevent loss of the low boiling constituents of the gasoline and to prevent the reaction between the nitric acid and the benzol from accelerating to a dangerous velocity.

As soon as this portion of nitrating mixture loses its strength, which it does after three or four alternate periods of agitation and cooling, the contents of the flask is removed to a separatory funnel and the acid separated from it. The gasoline layer is then returned to the flask, another portion of nitrating mixture is added to it, and the operation as just described is repeated. After this has been done a few times, three layers will form in the separatory funnel, only the upper of which is retained. The middle layer is a solution of nitrated benzene in gasoline, and the gasoline can be separated from it only with difficulty. In order to prevent this layer from containing so much of the gasoline that an insufficient amount is recovered in the upper layer the percentage of aromatics in a fuel to be examined by nitration must be kept below 50, by dilution with gasoline if necessary, as described above. When an intermediate layer no longer forms and the nitrating mixture after thorough agitation with the fuel remains colorless or assumes only a faint yellow color, the nitration may be assumed to be complete.

The nitrating mixture is separated and the gasoline layer is washed several times with sulphuric acid (sp. gr. 1.84). This washing is best conducted in a separatory funnel by agitating the gasoline with several successive small portions of sulphuric acid, separating the acid after each wash, and continuing the operation until the acid layer becomes only very slightly yellow. After washing once with water the gasoline is washed with small portions of a 30 per cent solution of sodium hydroxide until a yellow color is no longer imparted to the sodium hydroxide solution. Finally the gasoline is washed two or three times with water, and dried by filtering through a small amount of fused calcium chloride placed in a filter paper.

3—The specific gravity of the gasoline so obtained is accurately taken at 60 deg. Fahr. (15.5 deg. C.).

4—The percentage of aromatic hydrocarbons present in the original fuel is calculated as follows: (An increase in volume occurs when aromatic and paraffin hydrocarbons are mixed. However, it is not large enough to seriously affect the accuracy of this method from a commercial standpoint.)

0.879 (sp. gr. motor benzol)—Sp. gr. gasoline after nitration = A

Sp. gr. of fuel under analysis (see note)—Sp. gr. of gasoline after nitration = B

$B \times 100 = \text{percentage of aromatics (benzol)}$

**Note:** If the percentage of unsaturation of the fuel exceeds five, and it has been washed with sulphuric acid before nitration, as is recommended above, the specific gravity used here should be that of the fuel after the sulphuric acid treatment. (See above.)

Thus, if  
Specific gravity of fuel under analysis is 0.789  
Specific gravity of gasoline after nitration is 0.740  
 $0.879 - 0.740 = 0.139$   
 $0.789 - 0.740 = 0.049$

$\frac{49}{139} \times 100 = 35 \text{ per cent benzol}$

## 7—Purity of a Fuel As To Its Content of Paraffin Hydrocarbons

This test\* is conducted as described below, using the fuel after the unsaturated and aromatic hydrocarbons have been removed by nitration and washing as de-

scribed under the head, Methods for Determining the Content of Aromatic Hydrocarbons.

**Apparatus**—Thermometer with scale graduated by tenths of a degree from 0 deg. to 100 deg. C.

Test tube (6 in. x 1/2 in.).

150-c.c. glass beaker.

2 one cubic centimeter pipettes graduated to tenths of a cubic centimeter.

Flask and separatory funnel as given above under the head Methods for Determining Aromatics.

**Reagents**—Nitrating mixture composed of acids in ratio of 100 grams sulphuric acid (sp. gr. 1.84).

30 grams fuming nitric acid.

30 per cent solution of sodium hydroxide in water.

**Aniline.** The aniline should be freshly freed from water and decolorized by distilling from a larger quantity using direct heat, instead of steam for the distillation, and collecting the aniline for use as reagent while a thermometer in the vapor shows it to be distilling at about 183 deg. C. When exposed to light and air, aniline gradually darkens until it finally becomes black. Aniline light in color may be prepared from the dark material by distilling as described above.

**Method**—The fuel after nitration and washing for the determination of aromatic hydrocarbons as described above is treated at ordinary temperatures with two or three small portions of the nitrating mixture containing fuming nitric acid. It is then thoroughly washed with sulphuric acid, water, sodium hydroxide, water, and dried as described under Method for Determining Content of Aromatic Hydrocarbons. The fuel so obtained is used in this test.

An ordinary 6 in. x 1/2 in. test tube is fitted with a one-hole stopper and a thermometer so adjusted through the stopper that the bulb will be about 1/16 in. from the bottom of the test tube. From a 1-c.c. pipette, graduated to tenths of cubic centimeters, a sufficient amount of aniline is run into the test tube to cover one-half of the bulb of the thermometer.† An amount of the fuel under test equal to the amount of aniline used should then be added to the test tube. The total volume should be such that the bulb of the thermometer is completely covered. The stopper holding the thermometer is then put into the test tube and the whole placed in a beaker of clean distilled water over a gas flame, or on an electric hot plate.

The water should be stirred and heated slowly to such a temperature that the layers of aniline and fuel become completely miscible and perfectly clear. To aid in this the test tube should be frequently and gently shaken in an endwise direction. The beaker is then removed from the flame and the water stirred with the test tube using both a rotary and an endwise motion. As the water cools slowly a point will be reached at which a distinct and almost opaque cloudiness will appear in the test tube. At this point the temperature is quickly read to 0.1 degree accuracy, the tube being kept in the water all the time. An amount of gasoline equal to 1/5 of the original portion used is then added to the test tube and the determination of the dissolution temperature repeated as above. If the temperature at which the turbidity appears rises or falls more than 0.2 of a degree, the *critical range* has not been found. Aniline or gasoline is added to the mixture until the critical range is obtained. The highest dissolution temperature in this range is the Temperature of Critical Dissolution (T. C. D.) of aniline and the gasoline.

The highest temperature thus obtained (the T. C. D.) seldom varies more than 1 deg. C. from the Temperature of Dissolution (T. D.) of a 50 per cent aniline + 50 per cent gasoline solution. So that, unless a high degree of accuracy is desired, the work can be greatly facilitated by determining only the T. D. of a 50-50 aniline-gasoline solution, and using this value instead of the more accurate T. C. D.

If the T. C. D. of the gasoline is above its initial boiling point, as it usually is and as may be recognized by the gasoline in the tube beginning to boil before the solution of the aniline in it is affected, it is necessary to observe the following precautions:

1—A one-hole rubber stopper should be used for closing the test tube and holding the thermometer.

2—Care should be taken to heat the water to a temperature no higher than is necessary for the solution of the aniline in the gasoline.

\*The test described herein is based on the work of Chavanne, Simon and Dort, Comptes rendus, Vol. 168, pages 1111-4 (1919) and is supplemented with results of the experience of this Laboratory.

†The aniline pipette—which should be used only for aniline during the procedure—is conveniently kept through a hole made in the cork of the aniline bottle. In order to prevent contact of the aniline with air when not in use, the pipette itself should be stoppered with a small bit of cork.

Fig. 9—Standard 100 c.c. Engler Flask. Fig. 10—Long stem hydrometer, showing method of reading. Fig. 11—100 c.c. graduate. Fig. 12—10 c.c. glass stoppered graduated cylinder. Fig. 13—Meker Burner. Fig. 14—500 c.c. round bottom flask. Fig. 15—500 c.c. separatory funnel

3—Before opening the tube for the addition of more of the constituents the test tube should be cooled under the tap in order to prevent loss of gasoline as vapor.

4—If the gasoline has a very low initial, such as might be given by a casinghead blend, and boils in the test tube, it is best to place the entire sample in a clean distilling flask and distill until the vapor coming off has a temperature of about 60 deg. C. (140 deg. Fahr.). The residue in the flask may then be used in the T. C. D. determination.

If a highly accurate value for the T. C. D. of a very volatile gasoline is desired, it is necessary to make the determination in sealed glass tubes. For this purpose aniline and gasoline in varying proportions around the critical range suspected are placed in small glass tubes sealed at one end and having a constriction in the other end. These tubes are placed in a freezing mixture and sealed off at the constriction. Each in turn is then secured to the thermometer by rubber bands and the T. C. D. determined as above, using gentle endwise shaking and vertical stirring of the heating bath.

A determination made on an untreated gasoline gave this result.

C.c. Aniline	C.c. Gasoline	Temperature of Dissolution, Deg. C.
1.0	1.0	42.7
1.0	1.2	42.0
1.4	1.2	43.0
1.6	1.2	43.0 T. C. D.
1.8	1.2	42.4

### 8—Content of Alcohol

Because of the very great solubility of alcohol in water and the fact that it will not dissolve in gasoline alone if water is present, the detection and determination of alcohol in gasoline or gasoline-benzol blends is simple.

A 10 cubic centimeter graduated and glass stoppered cylinder (Fig. 12) is required. The determination is made in the same way as the percentage of unsaturation in gasoline as described above, except that water is used instead of sulphuric acid and that cooling is unnecessary. The amount of alcohol is read directly by the decrease in the volume of the gasoline layer.

### Specifications of Apparatus

**Important**—In order to obtain test results that are comparable with other laboratories, it is necessary to

use apparatus of the correct design. The following specifications cover such apparatus, and are standard as the equipment used for testing gasoline.

**Westphal Balance**—Shown in Fig. 7. To be accurate to the fourth decimal.

**Hydrometer**—Fig. 10. To be of the long stem type. Scale to be graduated from 0.700 to 0.800 at 60 deg. Fahr. (15.5 deg. C.). For benzol mixtures, scale to be graduated from 0.800 to 0.900 at 60 deg. Fahr. (15.5 deg. C.).

**Engler Flask 100 cc.**—Fig. 9. The prescribed dimensions are considered essential to attaining uniformity of results.

Dimensions as follows:	Centimeters	Inches
Outside diameter of bulb...	6.5 + or — .10	2.56 + or — .04
Inside diameter of neck...	1.6 + or — .05	.63 + or — .02
Length of neck .....	15.0 + or — .20	5.91 + or — .08
Length of vapor tube.....	10.0 + or — .20	3.94 + or — .08
Outside diameter of vapor tube .....	.6 + or — .05	.24 + or — .02

Position of vapor tube 9 cm. (3.55 inches) above surface of the gasoline when flask contains its charge of 100 c.c. The tube is approximately in the middle of the neck and is set at an angle of 75 deg. from the perpendicular. For safety, gasoline should be distilled only in a flask made from "Pyrex" glass.

**Thermometer**—The thermometer shall be made of selected enamel-backed tubing, having a diameter between 5.5 and 7 mm. The bulb shall be of Jena normal or Corning normal glass; its diameter shall be less than that of the stem and its length between 10 and 15 mm. The range shall cover 0 deg. C. (32 deg. Fahr.) to 270 deg. C. (518 deg. Fahr.) with the length of the graduated portion between the limits of 210 to 250 mm. The point marking a temperature of 35 deg. C. (95 deg. Fahr.) shall not be less than 110 mm. nor more than 135 mm. from the bottom of the bulb.

When the thermometer is made according to the Centigrade scale it shall be graduated in 1 deg. intervals. Each tenth degree shall be numbered and each fifth degree shall be distinguished by a longer mark. When made according to the Fahrenheit scale, it shall be graduated in 2 degree intervals, each

## List of Apparatus and Reagents Required for Testing Gasoline

	Approximate Cost		Approximate Cost
1 Electric heater for gasoline distillation .....	\$19.25	2 500-c.c. separatory funnels with glass stoppers..	3.76
1 Westphal balance .....	29.70	2 2-in. filter funnels .....	.44
2 Standard Engler distillation flasks .....	1.32	1 pkg. (100 sheets) 4-in. filter paper .....	.20
1 Standard condenser for distilling petroleum oils.	31.90	144 Corks for assembling distillation apparatus...	1.50
2 Gasoline thermometers .....	11.00	1 set cork borers .....	1.25
1 Thermometer, 0-100 deg. C. by tenths.....	7.15	1 pkg. cotton for thermometer bulbs .....	.15
2 100-c.c. graduates .....	.89	9 lb. sulphuric acid .....	1.87
1 Meker burner .....	2.64	8 lb. nitrating mixture, made with 1.42 nitric acid.	1.90
1 Burner connection, flexible metallic .....	.30	4 lb. nitrating mixture, made with fuming nitric	
1 Ring stand, 5-in. ring, and 5-in. table ring.....	1.76	acid .....	1.40
1 Burette clamp .....	.44	2 liters 30 per cent solution sodium hydroxide....	1.08
6 Test tubes, 6 in. x ½ in.....	.66	1 lb. fused calcium chloride .....	.80
2 1-c.c. pipettes, graduated by tenths .....	.46	1 lb. Aniline .....	.55
4 10-c.c. glass stoppered graduated cylinders.....	2.55	200 c.c. 1 per cent solution of methyl orange.....	.28
2 Pans for ice water baths .....	2.20	1 Asbestos board for gasoline distillation, 6 x 6 x	
2 3½" hemispherical copper dishes .....	1.98	½ in. with 1¼ in. dia. hole .....	.15
2 500-c.c. round bottom long neck flasks equipped		1 lb. rubber stoppers .....	1.65
with stoppers for nitration .....	.88		
2 Suberite rings for 500-c.c. flasks .....	1.43		
2 500-c.c. beakers .....	.55		
		Approximate cost of total kit .....	\$125.00

twentieth degree being numbered and each tenth degree being distinguished by a larger mark.

The scale shall be graduated for total immersion. The accuracy shall be within about 0.5 deg. C. (1.0 Fahr.). The space above the meniscus shall be filled with an inert gas, such as nitrogen, and the stem and bulb shall be thoroughly aged and annealed before being graduated. All materials and workmanship shall be the best.

**Condenser**—Fig. 8. The condenser shall consist of a thin-walled tube of brass or copper ½ in. internal diameter and 22 in. long. It shall be set at an angle of 75 deg. from the perpendicular and shall be surrounded with a cooling jacket of the trough type. The lower end of the condenser shall be cut off at an acute angle and shall be curved down for a length of 3 in. The condenser jacket shall be 15 in. long.

**Graduate**—Fig. 11. The graduate shall be of the

usual type, with a pressed or molded base and a lipped top. The graduated portion shall be for the quantity of 100 cc. It shall be numbered from the bottom up at intervals of 10 cc. Markings shall be for single cubic centimeters, and each fifth mark shall be distinguished by a longer line. The length of the graduated portion shall be not less than 7 in. nor more than 8 in. The distance from the upper graduated mark to the rim shall be not less than 1¼ in. nor more than 1¾ in.

**Heater**—If a gas burner is used it should be preferably of the Meker type, Fig. 13. Electric heaters especially designed for the distillation of gasoline may be readily obtained from reputable chemical supply houses.

**Graduated cylinder with ground glass stopper**—Fig. 12. 10 cc.

Polished hemispherical dish of spun copper approximately 3½ in. diameter.

## N. I. V. A. Discusses Difficulties of Farm Implement Industry

(Continued from page 754)

because some makers find a demand for it, but the question is if it would not be much better to eliminate it. The cost of carrying it is believed to be greater than the profits that come from its sales.

While the question of the farm implement dealer was not a subject discussed at the convention it came to the surface on one or two occasions. It was stated by one speaker that power farm equipment includes motor cars, motor trucks, isolated house lighting plants, as well as tractors and stationary gas engines and all that goes therewith. The natural conclusion was that the dealer selling all of this equipment was the logical farm equipment dealer; in a word, this is the type of dealer to sell to 40 per cent of the population of the country. For years our publications, *Motor World* and *Motor Age*, have been urging on the dealer the value of selling tractors and the other equipment that goes therewith. To-day some of the implement makers are approaching this from the other end of the line by including motor cars, trucks and isolated house lighting in the classification of power equipment for the farm, and at the same time are aiming to develop the power equipment dealer.

This dealer question is one that will be very much on the surface in the next few years and in reducing the

cost of all automotive products to the consumer we should keep in mind that of merchandising by not burdening our rural communities with several classifications of dealers, one for cars, one for trucks, one for tractors, one for house lighting, but rather follow the trend of big consolidations in the steel industry, in the meat packing industry, in finance, in publication work, etc. The cost of our apparatus to the consumer will be reduced by such consolidations and in so doing we are lowering walls of sales resistance and making it easier to own, operate and maintain our equipment, whether motor cars, trucks, tractors, house lighting, etc. Let us remember that new conditions make new methods necessary. For the new wine new bottles are essential. The old order of a score of years ago is passing and to succeed we must correctly interpret the needs of to-day. The situation calls for analysis rather than post mortems.

**P**UBLIC motor services in France are encouraged by Government bonuses. Thus the Minister of Public Works recently has granted Government subventions to lines in the Departments of Herault, Drome, Loire, Yonne, Correze, Doube, Ardeche, Cantal, Saone-et-Loire and Eastern Pyrenees.

# The Application and Manufacture of Silent Chain

A description of recent developments in applying chain to front end or distribution drives. Operation of automatic tension idler is explained. The manufacture of chain parts, their assembly and inspection, is outlined.

By J. Edward Schipper

**M**UCH has been learned during the past three years on front end chain drive installation for automobile engines. From all indications there will be more chain-driven front ends in the near future than we have at present, as there is a decided drift in that direction. It has been pointed out recently through these columns that practically all of the installations made on high-priced cars brought out during the past two years have been silent chain drive, and while it is admitted by car manufacturers and chain makers alike that perfection has not as yet been attained, there have been some distinct improvements which have been due not only to improvements in the design of the chain itself, but even more to the knowledge of how to install the chain and how to manufacture it.

Some of the installations which have been made recently are more or less revolutionary from a front end drive standpoint. The double-sided chain, automatic spring tension device and some new methods of making adjustments with the triangular layout are examples. These new types of installation give the designer a choice which enables him to suit any condition of auxiliary drive he is likely to encounter.

Chain life in the front end drive of an engine would be immeasurably increased if the high, momentary stresses could be eliminated. However, it is seemingly impossible to separate this condition of high momentary stress from internal combustion engine design as we now have it. With this condition prevailing, high factors of safety and accuracy are necessary. Where the accuracy of manufacture comes in, is not only to secure the proper spacing of the links and the proper action of individual links, but also to keep the contact line or the line of stress directly across the chain. An inaccurate chain will squirm, because the line of stress moves about, with a result that it is noisy and short lived.

There are certain inherent advantages to a chain drive which can be fully realized if the chain is accurately

manufactured and properly designed and installed. In the first place, quietness is readily secured in this type of installation, when the proper type of installation is selected. Probably the greatest advantage of chain drive, however, is the introduction of an elastic element into the drive which absorbs vibration that a positive drive would transfer to the housing. To put this in another way, a great many of the timing gear noises which are charged up to the front end drive are simply transferred to this drive from other parts of the motor and do not originate in the timing gearcase at all. This condition is not so apt to prevail with an elastic type of drive such as the chain.

Another definite advantage is the ease of overhauling and restoring the front end drive to its exact original condition. Adjustability in a chain drive is, of course, highly essential, and engineers should not countenance a design in which there is not an adjustment feature of some sort to take up initial stress and wear.

The qualities necessary to accomplish the results outlined in these requirements must be built into the chain if good results are to be obtained. These are the basic requirements of chain design and form the fundamentals which have been considered in the working out of the chain types. The Link-Belt chain with which this article is concerned, is now being made up in a new type which is known as the unit chain and which is suitable for single-sided contact drives. This unit type of chain will shortly be in production at the Indianapolis plant and has a great many unique features which are of great interest.

The unit chain is so-called because the individual links combine the functions of spacing as well as of the bushings. It has been intended in the design of the Link-Belt unit chain to impart extreme uniformity in each part in order to insure absolute load distribution and no change of stress direction or weave as each succeeding row of links comes into contact with the sprockets. There are spacing lugs on the links to keep the stress line at

Fig. 1—Link-Belt chain and units of which it is composed

Fig. 2—Link-Belt automatic tension governor for front end drive

all times straight across the chain and equally distributed, this being a most necessary requirement in order to prevent weaves in the chain as it passes around the sprocket in performing the driving function.

One of the main features of the unit chain is that it presents a continuous surface to the sprocket rather than a broken one. This property, it is claimed, resists rough action and also maintains the oil film. Maintenance of the oil film permits cushioning of the drive and consequently much longer life on the chain. It is claimed that the oil film will not break on this type of chain because the continuous surface is far more conducive to maintaining the integrity of the film than is the case with a broken surface which would permit the oil to escape much more readily. In the unit type of chain there is no bushing. The continuous bearing for the pin is coined integrally with the links, which gives equal pin bearings to each length and allows each link in the chain to do a uniform and equal amount of work. The individual links, as well as the entire chain assembly, is designed to put in the qualities necessary to resist the stresses peculiar to camshaft drives.

Some interesting installations of Link-Belt liner type silent chains have been made by the use of the double-sided chain in which some of the links are reversed in order to provide a bearing surface on both sides of the chain. This permits a greater flexibility in design layout, particularly in the drive of auxiliaries. It is possible to obtain sufficient wheel contact with the double-sided chain with shafts in a position where it would be practically impossible to secure the desired amount of contact in any other way. An installation of this kind makes it practically impossible for the timing chain to jump a sprocket tooth as has been known to occur with installations where the chain has not had sufficient contact with the sprocket wheels. The double-sided chain permits of a reverse bend in the chain, which allows it to wrap itself around the wheel with a far greater area of contact than would be possible in any other way. This feature is very clearly brought out in the illustrations accompanying this article on the use of the double-sided chain.

Another installation feature which provides the engineer with greater elasticity of design in using the Link-Belt product is the automatic adjustment device. This includes a tension governor which compensates for wear. The functions of the automatic adjustment are, maintenance of proper tension in the chain; compensation for elongation; increase of effective angle of driving contact; insurance of smooth engagement between the chain and the wheels; elimination of vibration or whipping

from the chain; and reduction of the amount of attention it is necessary to give the chain in service. The automatic adjustment feature is shown in the sectional drawing, Fig. 2. This is an eccentric device with a spring mounting to maintain constant tension in the chain. The stud, A, is mounted rigidly with the timing gear-case. The eccentric, B, on the stud carries the wheel, C. When the eccentric, B, rotates the wheel, C, moves, regulating the tension in the chain. The amount of tension is controlled by the flat clock spring, D, which is anchored by means of the collar, E, and adjusted by the exterior adjustment nut. The device is lubricated by oil which enters the center of the shaft, as shown in the section. The variety of installations permitted by these different types of layouts permit taking care of any sort of arrangement of the main and auxiliary front end drives.

The manufacture of silent chains is of particular interest because the individual units are very small and yet must be highly accurate. It is self-evident that any error in accuracy in chain manufacture is cumulative; that is, it builds up with the length of the chain and consequently presents a problem in accuracy which is second to none in the line of automotive parts. Link-Belt chain is manufactured from strip alloy steel. This is 3½ per cent chrome nickel stock and for the automotive front end drive chain, which is ¾ and ½ in. pitch, the strips come in lengths of about 100 ft. Practically all of the machinery used in the manufacture of Link-Belt chain has been developed at the Link-Belt factory and is of a highly specialized character.

The initial operations in the manufacture of the links are the perforating, broaching and blanking. The tool equipment for these three operations is shown herewith. The punches and dies are the only details which differ from those shown. The operation illustrated is broaching. The inspection gages for the operator are shown on the table of the machine. This punch press, which is a Ferracute, operates at the rate of 120 strokes per min., and hence turns out links at the rate of 2 per sec. The strip steel utilized for this purpose is 1 in. in width. An interesting feature of this machine is that the punch pins are longer than the other cutting tools, thereby permitting them to act as locating points. This operation, as well as the majority of operations which follow, is taken care of by girl operators.

After the links are blanked out, they are "shaved" to size. This shaving operation removes metal from all around the outside of the links and makes the edges square with the flat side of the link. The machine is fed by a centrifugal feed hopper, which system is used quite extensively in handling the great number of small links which the machines are required to take care of in the manufacture of the chains. The shaving operation is held to very close limits, as this squares up the entire link and is really one of the vital points in the manufacture of the chain. The centrifugal hopper whirling around throws the links into the feed channel and a scoop device is so arranged that the links cannot enter this channel upside down, but have to go in the desired position so as to be ready for the shaving tool.

The liner type of Link-Belt chains, not the unit type mentioned, employs a chrome nickel steel bushing. The stock for this bushing, which bears upon the chain pin, is strip steel. The first operation on the strip steel is to shear it into more narrow strips. This is accomplished in one operation, the shears splitting the stock into three parts. These narrow strips are then cold rolled to a partial round and this partial round is straightened and cut off to size. This work is done on special machines designed by the Link-Belt Co.

3—Double sided Link-Belt chain installation as used on the new Haynes car incorporating the automatic tension governor. 4—Typical triangular Link-Belt chain arrangement as used on the Rochester-Duesenberg. 5—Automatic tension governor with single sided chain as used on the Mercer. 6—Link-Belt chain installation employed on the Chandler.

The washers which hold the links in position are automatically punched from strip stock. The washers are embossed in an automatic embossing machine and then are sent, together with the bushings and links, to what is known as the "laundry." This consists of a series of tumbling barrels where the various parts are given wet and dry washes to prepare them for heat treatment. A feature of the laundry is the use of heat on the tumbling barrels. These are heated by a flame which plays on the side of the barrel while it is rotating.

The heat-treating furnace is particularly interesting in that it is automatic in its operation. The furnaces are the Bellevue rotary and are electrically heated. They are pitched on an angle so that the parts gradually rotate down to the bottom in the proper time and then drop into the oil quench. The parts which are quenched are conveyed automatically up through the oil and dropped into trays from which they are transported back to the laundry and recleaned.

There are two heat-treating operations. The parts are first packed in compounds in pots and put into the Bellevue furnace, after which they are cleaned and then returned to the heat-treating room and put into cyanide furnaces for hardening. The links are given a 1/64-in. skin. They are taken back to the laundry after this final hardening process and given a wet wash to thoroughly clean them to make them ready for assembly.

The pins and bushings are brought to a group of girls who straighten them. These girls use little steel mallets to hammer the pins and bushings which are not straight against flat plates. They are very expert at

detecting any lack of straightness in the parts and know just where to strike the part to straighten it out.

The links are given an automatic inspection in a machine which is provided with a rotating hopper which throws the links into a feed channel in the same way as was previously described for the shaving operation. The links then pass down through this channel and if they are not exact in straightness or size, they are automatically discarded. Only perfect links are permitted to pass through the machine into the barrels below.

One ingenious operation is accomplished by the device for softening the ends of the pins so as to make them easily riveted over in the assembled chains. A machine with a rotating wheel of sufficient width to pick up the pins in a sort of sprocket tooth arrangement on the periphery is employed. The pins are fed into this wheel and guided so they project over on each side a definite amount. A gas flame plays on the part of the pin which projects over the outside of the wheel. As the wheel goes around, the pins drop off into the water, the rotative speed and the diameter of the wheel being so calculated that the ends of the pins have been subjected to the temperature of the gas flame for just the proper length of time. The pins are then placed in a centerless grinder and rolled between two grinding wheels to give them the exact finish size. This is a specially designed machine made at the Link-Belt plant.

This completes the manufacturing operations and brings the various units of the chain up to the point where they are ready for assembly. The pins, links, bushings and washers are all in pans, accurately checked

7—First three operations. Perforating, broaching and blanking. The same tool equipment is used for all three operations, the only details that differ being in the punches and dies. The operation illustrated is broaching. The operator's inspection gages are shown. 8—Shaving operation with centrifugal feed hopper. Shaving removes the break-out from the periphery of the links, making the edges square with the flat side. 9—Cold rolling the bushings for the liner type Link-Belt chain to size. 10—Automatic link inspection machine which only allows perfect links to enter barrel. Rejects are caught in small scoops shown at sides. 11—Annealing the edges of the pins to make riveting possible. Note how ends of pins extend over side of wheels so that gas flame comes in contact with proper links. 12—Automatic machine for embossing the washers

13—Tumbling barrels for cleaning parts before assembly. 14—Heat treating links in automatic furnace. Note pyrometer indicator for operator. Operation of furnace is continuous, the only function of operator being to fill the feeding hopper and adjust burners. 15—The link assembly is built up in links of 1 ft. in the jigs shown herewith. 16—Inserting pins and bushings in liner type Link-Belt chain after cover has been put on jig. 17—One foot lengths as assembled in jigs are connected with 10 ft. lengths which are placed in articulators and are run-in to take up the initial elongation. 18—Final inspection of chain. This photograph was taken with the chains running

with the number of pounds in each pan. The chain is assembled in 1-ft. lengths in assembly jigs.

The assembly jig is in two parts, one part where the links are put in place and the other is a cover plate which slips over the jigs and holds the links in proper position while the pins and bushings are pressed in place.

The 1-ft. lengths of chain are then given a careful inspection and the chain is then assembled in 10-ft. lengths and subjected to a running-in process. The machine on which the 10-ft. lengths is run contains a soda tank and the chain is run in the solution. This machine is so designed as to provide an adjustable center distance for the 10-ft. lengths, and the chain is first run slack and then gradually brought closer and closer to pitch. The soda solution takes all of the dirt from the chain, while the adjustable center distance brings the chain up to its final size, giving the chain its initial stretch, due to taking up the slack parts.

After the 10-ft. length has been run in on this articulator, the chain is given an inspection measurement and must check up accurately to gage. The chain is allowed to run from 35 to 40 min. on the 10-ft. lengths. After inspection it is torn apart and assembled to its proper length. It is inspected for tight joints, the rivets are all gone over carefully and it is given another run in

its finished length at the proper center distances before it is finally tagged as O. K.

One of the laboratory test devices which is located in a silence room consists of a frame with slots running at all angles, making it possible to make any type set-up and run the chain at all inclinations and angles. It has been found that chains may be silent in one position and after slightly rotating the test block, noises may develop. Inasmuch as in motor car service the inequalities of the ground cause the chain to be operating at various angles of inclination, this is an important point.

In connection with the chain plant, there is a laboratory in which it is possible to run the chains under very severe conditions, submitting them to endurance tests under stresses which are far higher than anything that would be encountered in actual service. This has resulted in break-down figures for a number of types of chains which give an accurate clue to causes of chain failures. One of the most interesting points which has been brought out by photo-micrographic study and other methods is that the line of weakness in a chain under static conditions is entirely different from that which develops under dynamic conditions. The point of failure under dynamic conditions does not at all correspond with the point of failure under static conditions.

## A Demountable Body Carriage

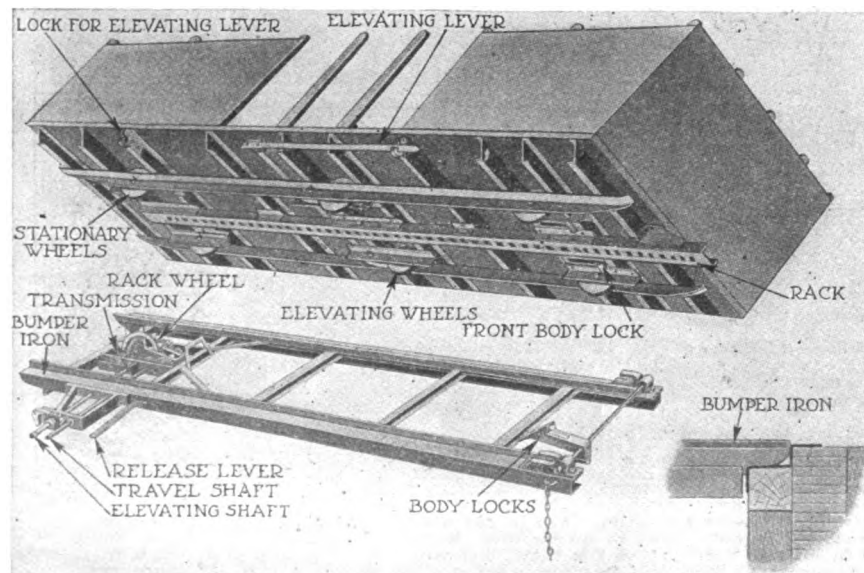

AS a labor and time-saving device in truck transportation the demountable body has been used successfully in many instances. While their production is not general by motor truck manufacturers it is quite likely that more buyers will demand this form of body within the near future. In some cases several operations can be carried on with one truck at the same time when two or more demountable bodies are employed.

One man can load or unload a body carrying from a 2½ to 8-ton load by means of equipment, manufactured by the Ideal Truck Equipment Company.

The carriage for the removable body comprises a steel framework attached to the chassis and a similar framework attached to the bottom of the body. These frames consist of two channels each, supported by cross

members. Small wheels are attached to the upper channels on the body, and these may be raised or lowered at will by means of an elevating lever. A rack runs down the center of the body framework. In the rear center of the chassis frame is a rack wheel operated by a crank. There is also an elevating shaft that makes it possible to raise or lower the framework to the level of the surface upon which the body is placed before loading. Bumper irons at the rear ride over a stringer attached to the loading platform, thus maintaining the tracks flush with the platform.

When the truck is backed to the loading point the body is rolled forward until the rack is above the rack wheel when it is lowered until the two engage. By turning the crank body is brought forward to its proper position, the locks are snapped in place and the load is ready for its journey. The same method is used in unloading.

Ideal Truck Equipment Company's demountable body carriage

AN investigation regarding the preparation and uses of metallic zirconium and its salts has been conducted by the Bureau of Mines and the results are just now made public.

Coherent white zirconium metal, on account of its acid-resisting properties, has been suggested as a substitute for platinum in certain cases. Crucibles prepared from zirconium oxide were proved in the experiments of the Bureau of Mines to be superior for high temperature work to any crucibles procured on the market.

The results of the investigations of the Bureau of Mines are available in Bulletin 186, "Investigations of zirconium with especial reference to the metal and oxide," by J. W. Marden and M. N. Rich, which is distributed by the Superintendent of Documents, Washington.

# Government Aid Necessary to Foreign Commercial Flying

British and French aerial navigation companies find present costs of operation far above revenues from passenger rates. Four types of machines considered best for various services in France.

**E**XISTENCE of companies operating passenger and freight airplanes in France and England is largely dependent upon government subsidies. Present operating costs are so high that were these navigation concerns to depend solely upon revenues received in passenger and freight rates they would be forced to discontinue business or else increase their prices to a prohibitive figure.

Official figures show that the present cost of operation on regular passenger carrying services is about 10 francs per kilometer for single-engine planes of 300 hp., and 15 to 16 francs per kilometer for twin-engine planes having two motors of 260 hp. each. Taking as an example the Paris-London service, distance 250 miles, operating to 80 per cent of schedule in summer and 70 per cent in winter, the receipts per kilometer are made up as follows:

*Twin-Engine Type Machine, Farman Goliath, with Two 260-H.p. Salmon Engine, Carrying Two-Thirds of the Maximum Load, or Six Passengers and 440 Lb. of Goods*

For passengers and freight, per kilometer....	Fr. C.	
Flying subsidy .....	8	00
Efficiency subsidy .....	5	50
	14	00
	22	00

*Single-Engine Type Machine, Breguet, with 300-H.p. Renault Engine, Carrying Two-Thirds of the Maximum Load, or Three Passengers and 66 Lb. of Freight*

For passengers and freight, per kilometer....	Fr. C.	
Flying subsidy .....	3	00
Efficiency subsidy .....	4	50
	7	00
	10	00

Experience shows that all the advantages lie with the big multi-engine plane, the mileage earnings of which are sufficiently high to assure the success of the operating company, on condition that passengers are always available and that weather conditions permit of a regular service. The subsidies available under the French scheme are equal to two-thirds of the total earnings, and with these subsidies it ought to be possible to reduce present passenger fares and freight charges by 25 per cent.

## Results of French Experience

The lessons learned from commercial airplane service in France are that the following special kinds of machines should be developed:

**Passenger carrying plane:** Multi-engine plane with at least three engines, capable of flying with one engine shut down, landing easily and taking off quickly, a wide range of speed, coefficient 6, engines easily accessible while in flight, engines capable of 120 hours' flight without overhauling, mechanical starting, ability to fly under full load for five hours, equipped with a cabin for the crew, wireless cabin, passenger cabin 78 x 70 in. Ceiling, 13,000 ft.; speed at an altitude of 6500 metres, 125 miles an hour; total tonnage, 1½ tons, and radius of action, 560 miles.

**Postal Plane.**—Single-engine machine with a wide range of speed, coefficient of security 8, mechanical engine starting, ability to fly four hours under full load; pilot's cabin, mail-hold to receive 5 mailbags weighing 90 pounds each; practical ceiling, 13,000 ft.; speed at 6500 ft., 155 miles an hour; fuel for four hours' flight; useful load, 450 pounds; radius of action, 500 miles.

**Touring Plane.**—Single-engine plane carrying two passengers and 200 pounds of baggage. This plane should be easy to pilot, of all-metal construction, having a coefficient of security of 5, and an engine capable of operating 150 hours without overhaul. Fuel consumption less than 6 gal. per hour's flight at full power; five hours' fuel supply; practical ceiling, 10,000 ft.; speed at 6500 ft., 125 miles an hour; useful load 330 pounds; radius of action, 450 miles.

**Commercial Flying Boat.**—Multi-engine plane capable of flying with one of its engines stopped at a height of 1500 ft. for two hours with its full useful load and two hours' gasoline. Ability to navigate on the water until the entire gasoline supply is exhausted; useful load, 1 ton; cruising speed, 80 miles an hour; maximum speed, 100 miles an hour. Gasoline supply for five hours' flight at full speed; cabin for eight passengers separated from the baggage-hold; gasoline tanks separate from the hull; engines readily accessible when in flight; mechanical engine starting; wireless transmitting and receiving set capable of carrying 180 miles; coefficient of security 6; radius of action, 500 miles.

## Military Types Predominated

Practically all the French commercial planes in service during the past year were military types or modifications of military types, the only important exception being the Farman twin-engine Goliath, which is now being replaced by a rather bigger type with three engines. The new big capacity commercial planes under construction and likely to go into service at an early date are the Bleriot Mammoth with four Hispano-Suiza engines of 300 hp. each, total weight, 7½ tons; speed, 93 miles an hour, and the Breguet Levathan, with four Bugatti engines of 250 hp. each; total weight, 6¼ tons.

**A**CCORDING to *Der Rationelle Werkbetrieb*, the well-known German light alloy, duralumin, which is much used in aircraft construction, can be refined and toughened by quenching as well as by cooling in the air. Strange to say, however, it must be allowed to season for four days after the heat treatment is completed. An approved quenching bath for duralumin consists of a 10 per cent solution of sodium hydrate at 30 deg. Cent., in which the metal is allowed to remain for five minutes. This is followed by a bath consisting of three parts of nitric acid, one part of sulphuric acid and twelve parts of water. The parts must be well rinsed.

## Grinding Splined Shafts

Editor, AUTOMOTIVE INDUSTRIES:

Referring to the article in the Sept. 15 issue with reference to "Tolerance Allowed in Grinding Splined Shafts," I wish to take issue with the author thereof in regard to some of the statements made.

The article states: "It will be noted that the bearing is solely on the ground surface of the inner diameter of the fitting." True. But the said "ground surface" is commercially obtained only by a process claimed to be covered by patents.

It also states that: "It is an easy operation to grind the bore of the spline fitting." True, if the hole happens to be a comparatively short one as in a gear. But how would you grind on a commercial basis a hole  $4\frac{1}{2}$  to 5 in. long, and from 1 to  $1\frac{1}{4}$  in. in diameter as required in the propeller shafts? Of course, such grinding can be done if you wish to pay the price, but it is not necessary in order to get a satisfactory spline fitting, and if adopted would add an unnecessary additional cost burden.

Regarding life of broach with .001 in. tolerance on the O. D. if a good finish with accurate width of spline is to be maintained, a rebroaching or "finishing" cut will in most cases be required. If the limits of the width of the splines, parallelism, and finish are to be maintained comparable with .001 in. tolerance on the O. D., the latter will not cause serious additional trouble or expense. The rebroaching may be done with either a special finishing broach or with a standard broach which is later used for roughing, after it becomes dull enough to require re-sharpening.

Regarding the advantage claimed for lubrication, a clearance on the small diameter is of even greater value from a lubrication point of view than is a clearance on the large diameter.

If the methods and suggested tables of fits suggested were to be adopted as standards by the Society of Automotive Engineers, much unnecessary expense and patented methods would be thrust upon the makers of automobiles without any commensurate return, and the implication the article carries that the Society of Automotive Engineers or other organizations have been derelict in adopting these or other similar shaft dimensions, I believe to be not warranted by the facts.

The idea of such shaft standards is not new, such suggestions having been made and discussed on several occasions in S. A. E. meetings. Every time, however, that this subject has been brought up for discussion in the meetings of the Standards Committee or of the Society, leading and well known engineers have stood against such attempt of standardization for the reason that a spline fitting contains many surfaces which are sure to change their relations to greater or less extent with heat treatment. The question has been raised as to whether the close fit should be on the large diameter or on the smaller diameter. The actual determination of this question must depend upon individual requirements and shop equipment and will depend upon what surfaces, if any, are to be ground after hardening, whether the fit on the sides of the splines

should be free as in transmission gears or very close as in propeller shafts, whether one or both parts are to be heat-treated after machining and whether one or both parts are to be ground after heat treatment. From this it will be seen that if standards for the shaft ends were to be adopted, it would be necessary to very greatly extend the scope of the standards proposed by the article referring to the Gear Grinding Machinery Company's practice, as many spline parts are heat-treated before machining and, therefore, require no grinding, while many other spline parts are used where the conditions do not require the refinement of grinding. In many instances, also, one part of the spline fitting is hardened after splining, while the other part is left comparatively soft. Therefore, when the subject has come up for general discussion, the action after discussion has always been unanimous or nearly so, to the effect that all that can be accomplished in the way of standards is the standardization of the broaches, and, consequently, of the soft broached holes, but that material to be allowed for the grinding processes employed and character of the fit required must necessarily leave the other limits and tolerances to the judgment of the individual designing engineer.

Spicer Mfg. Corporation.

## Fan Dynamometers

Editor, AUTOMOTIVE INDUSTRIES:

Your editorial in the September 15 issue on the use of cradle type fan dynamometers directs attention to an extremely important phase of modern engine production in the automotive field. The fan dynamometer must have its chief usefulness as a production device, which is to say that the testing under load of every engine produced is of such importance as to warrant a thorough study of proper testing means.

A weakness in our passenger car industry to-day is the lack of proper tests of completed engines and cars. In many instances reliance is placed merely on careful inspection during manufacture. Many dealers have stories to tell of cars delivered from the factory which require expenditure of a considerable sum to put right, because they were not made right before they were shipped.

This is notably the case with cars in the medium-priced field. A carefully considered testing schedule which positively detects defects before cars get in the hands of users is bound to react to the standing of the manufacturer in the eyes of his dealers and his public, and is as well worth the cost in the medium- and low-priced field as in the high-priced field, where such tests are now regularly employed.

When it comes to considering the method of testing for production purposes, however, it is not clear that a fan dynamometer of the cradle type is the solution. Already a large number of plants have installed the simplified "electric block test" system. The result is a working schedule which provides not only for the loading of the engines but for the adjustment of this load

through a wide range while the engine is in test in order to meet the requirements of a progressively increasing load as the engine works in. Measurement of friction horsepower is provided for, which is a very important factor in building new engines, as it sets a definite standard of assembly; friction being held to a definite minimum on test. There is also, with the

electric method, a large saving by the utilization of electric energy in the shop. The importance of this last factor has been emphasized during some winters which are fresh in our memory, when coal was hard to obtain and the plants which had the electric block test system could keep running.

SPRAGUE ELECTRIC WORKS,  
C. F. Scott, Manager, Apparatus Sales.

## The Automobile in Peru

OF the 3000 automobiles and trucks in Peru, perhaps 2000 are in Lima, the capital. The majority of the streets of the city are in poor condition, being paved with round pebbles, gathered up along the seashore. The public square, however, has recently been paved with asphalt. The main business street and one of the leading avenues is also asphalt. Through these two streets the automobiles pass out to a drive along the seashore between Lima, the capital, and the suburbs, Miraflores and Callao. This drive, called the Miramar, is in fair condition, partly paved with pebbles, but if not continually repaired, will soon become unsuitable for automobiles. The automobiles outside of the capital, as far as roads are concerned, do not fare much better than those in it.

It is impossible to give the exact distribution of the automobiles and trucks outside of Lima, but, in the main, they are situated in, and in the vicinity of the following cities:

Chiclayo .....	175.
Trujillo .....	125
Tarma .....	30
Cañete .....	146
Arequipa .....	99
Ica .....	199
Chincha .....	190
Scattering .....	36
Total .....	1000

The "scattering" will be found in Huacho, Supe, Pacasmayo, Cerro de Pasco, etc. In these cities themselves, except those situated near the oil belt to the north, where petroleum has been used to improve the roads, very little has been done for the streets. The roads around these cities, where not impassably rough, are mere stretches of sand.

The automobiles now in Peru, as they have mostly come in during war time and immediately since the war, are largely of American make. There are present a surprisingly large number of the higher grade American cars. Travelers who have visited Lima state that, in proportion to the total number of cars in Lima, there is no other city that has so large a number of high grade cars. Indeed, it is only recently that the popular-priced American car has come to its own in Peru.

The European car is present also and its numbers will doubtless increase as the factories in Europe recover from the effects of the war. The principal English, French, Italian and German cars are now represented.

With the truck, the European manufacturers are making more headway than with the automobile. Many big European trucks have been put in service within the last year and may be seen on the streets of Lima. Two large trucks of a well-known French make with passenger bodies have just been put on a direct route over a new macadam road between Lima and Miraflores, a dis-

tance of some nine miles. Miraflores is one of the bathing resorts of the capital and the suburb where reside most of the foreign residents of Lima. These two passenger buses will have to compete with the interurban electric line, to some extent, although they traverse slightly different districts.

Owing to the unfavorable exchange rates, the Peruvian pound having lost one-third of its purchasing power due to the fall in the price of sugar, wool, cotton and copper and the consequential lack of exportation of these products, few automobiles and trucks have been imported from the United States this year. When exports pick up and exchange improves, there should be a market here.

Although Peru is suffering along with the other countries of South America and the world from financial depression, the month of July in Peru has been a glorious one for the automobile dealer. The reason for this is that during July was celebrated the 100th year of the Independence of Peru and every one who could purchased an automobile as the best possible way in which to signalize an event of such far reaching importance.

## Protests in French Fuel Economy Contest

IN a letter addressed to *La Vie Automobile*, Goudard & Mennesson, manufacturers of the Solex carburetor, complain of some of the practices pursued in the recent French fuel economy contest. It appears that one of the contestants asked the management six weeks before the contest whether it would be permissible to draw the air for the carburetor through the crank chamber containing the lubricating oil. It was decided by the management to modify the regulations so as to permit of this, and all contestants were notified ten days in advance of the contest of this change in the rules. The following day the Solex firm sent a written protest against what they are pleased to call "this tomfoolery," of carbureting the crankcase oil, which is maintained in a state of ebullition by means of an electric current, the cost of which is not taken into account in the classification. The amended rules, they say, even provided for a reserve oil tank on the footboard for use in case the contents of the crankcase should not suffice.

They refuse to admit the argument that in two-stroke engines the combustible charge, carrying a certain amount of oil, is drawn through the crankcase, as in this class of engine the oil is mixed with the fuel in advance and is therefore measured with the fuel. They do not care, they say, what kind of fuel is used as long as it is measured, but they ridicule the plan of burning lubricating oil at 4 francs per 5000 calories instead of benzol at 2 francs per 10,000 calories. Automobile manufacturers have remained entirely ignorant of this practice, which was instigated by a carburetor firm looking after the technical adaptation of the vehicles.

# Choosing Men Through Employment Departments

Larger organizations find specially trained men for employment managers valuable, but the necessity of close contact with supervisors within the plant is pointed out. Present status of employment departments is more or less unsatisfactory but proper development would increase efficiency.

By Harry Tipper

**T**HE analyses of labor turnover which have been made from time to time have indicated the necessity for some means of selecting employees, so that the expense of hiring and firing could be reduced and the stability of the organization personnel increased accordingly.

In large companies the employment department is very actively engaged in making records of the various applicants, keeping close to the developments, and endeavoring to sort out in a preliminary way, at least, those who are more efficient and more desirable. In fact, this work has gone forward to such an extent that a bibliography of a number of books has grown up dealing with the employment, the management of employment bureaus and the general method of selecting employees. Tests have been prepared intended to indicate the alertness, the potential value and the other characteristics of the worker outside of those involved in his skill.

Where thousands of employees are being handled with the usual percentage of turnover per month, the possibilities of selection are correspondingly reduced. Such a section of the skilled and unskilled occupations makes it impossible to reach a high average of efficiency by selecting from the general number of applicants those who are more capable. In the ranks of twenty or twenty-five thousand employees, the general differences in skill and potential capacity will be about in the same proportion as those obtaining throughout the number engaged in such occupations.

In the case of each individual concern, however, the attempt is made to select employees to represent as large a proportion of the more efficient and capable as it is possible to secure, and this is the main purpose of the employment bureau with its systems of examination and its continuance of record.

In the larger organizations it has been felt that selection of employees by a department specially trained for that purpose and carrying the responsibility for the selection results in a better general type than where the selection of the employees is left to the individual supervisor.

The results have not been entirely satisfactory, however, and the turnover has not responded to these methods of selection in any notable way. Of course, many of these employment bureaus have been successful to a degree in improving the situation that obtained previous to their establishment, but this fact is not sufficient to justify the endorsement of the method nor to illustrate the value of the various systems now in use by these bureaus.

One of the difficulties in connection with this development is the tendency for the work of selection to become extremely technical and mechanical in its application so that the tests and examinations become sufficient in themselves and not merely indications.

Obviously, the applicants for work at a large factory represent a sufficient number at any time to make the work of personal interviewing difficult, if not impossible, and the only method at present available is the method of record and examination by standards, written tests and questions.

Able men have been successful in the use of these systems and in drawing from them a great many of the factors required to determine the relative value of the different applicants.

The tendency to accord to the system the success of the development has been great and this tendency has emphasized the system beyond the actual facts and led to its adoption where the conditions would not warrant its development.

In the selection of employees it is desirable to consider, from a human standpoint, the factors that make up the efficiency of a department and the stability of employment therein.

Previous to the development of employment bureaus, the work of hiring was left as a rule to the supervisors in each different department of the organization with the result that there were as many methods of hiring as there were supervisors. There was no co-ordination and the man who was proved unsatisfactory by one supervisor was found to be satisfactory under another.

Under these circumstances men were hired and discharged from one department without having any opportunity to get into work in any other section of the company and with a considerable loss to the company for the time spent in adjusting the employee to the organization. Cases of injustice were more or less frequent and personal grievance of the employee toward the supervisor was a cause of trouble at all times.

These conditions led to the establishment of the employment departments with their regular methods of selection and in some cases with the records and considerations of promotion. A great deal has been gained by this change and a certain amount has been lost.

The factors required in the selection of employees for a particular department are:

1. The requisite skill in the work.
2. The desire for permanent employment in one place.

3. A sufficient measure of adaptability.
4. Possibility for harmonious contact with the supervisor.
5. The ability to work co-operatively with other men.

The proper adjustment of these values in the selection of the employees depends upon the supervisor as much as upon the employee selected.

#### The Supervisor As Employer

Where the selection is undertaken by a different man from the supervisor, the sympathy with the employee is not quite as definite as it should be. Furthermore, the sense of responsibility is not as definitely placed upon the supervisor, and the patience which must be exercised in adjusting new employees to the organization so that the greatest efficiency can be secured is not always visible under these conditions.

In some cases this objection has been met by the employment bureau acting to select the workers for the approval of the supervisor after the preliminary selection has been made.

The advantages secured through the establishment of employment bureaus have been secured in the face of almost a total lack of education of supervisors in the problem of securing a sound co-operative organization among the workers. Until the last two or three years practically nothing was done to educate the foremen and other supervisors in the factory, while in the commercial end of business nothing of importance has been done up to the present, except in a few individual cases.

So long as the supervisors are not educated in the fundamentals of good organization and the methods of handling employees, the specialized department devoted to the selection of employees is a necessary matter in the large plant and cannot be dispensed with very well. It will not entirely solve the problem, however.

The selection of employees is limited to the available material, so that it will vary according to the extent of employment through those occupations, and a selection in this manner does very little to provide the preliminary possibilities of permanency and efficiency in the organization condition.

Most of the plants in the United States in point of number do not have a sufficiently large payroll to require an employment bureau exclusively for the purpose of selecting the employees. In these cases, however, the matter is not handled more efficiently as the usual procedure is to designate some one or two persons to interview the applicants, take such records and tests as have been decided upon, and submit these to the su-

pervisors or notify the supervisors that such workers are available.

There are notable exceptions to these conditions in the different branches of the metal trades industry, but the methods of selecting employees have not received the study given to the selection of machinery or other mechanical appliances, nor have they affected the efficiency of the employees or the permanence of employment in any considerable degree. Here, as in other cases in connection with the human relations problem in production, the systems and mechanics of organization have been permitted to stand in the place of judgment and understanding to a considerable extent.

No method of selecting employees can take the place of the personal interview where the interviewer is sufficiently able to put the applicant at his ease, to draw him into conversation and secure from the casual reactions the actual tendency of his interest and capacity. The mechanical skill required of the individual can be determined with comparative ease. The other qualities cannot be so readily discerned. They can be discovered only through the exercise of considerable judgment on the part of the interviewer with a careful understanding of the conditions of the interview.

Employment bureaus in the larger establishments and the employment officials in the smaller establishments cost a great deal too much if their value is confined to the routine of recording expenses and securing answers to test questions. On the other hand, employment bureaus that function with understanding, knowing the supervisors, their methods of operation and their personal idiosyncrasies, would be worth a great deal more than is now expended upon the employment bureau, because of their ability to increase the permanence and efficiency of the general organization.

#### A Matter of Guesswork

The selection of employees is largely a matter of guesswork even with the best of the present systems and with all the ability to be secured under normal conditions. This guesswork should be recognized and the speculative factors understood in dealing with the situation, so that the systems of selection are not called upon to perform functions that they are not capable of fulfilling.

They are useful in their way. They are a great deal more useful for what they prevent than for what they secure, but they are by no means justified in their present condition by the general situations, and further analysis is necessary to produce the kind of employment selection that will make for effective organization.

## Convenience in Car Bodies

BRITISH manufacturers, as well as those in other countries, are scored by a correspondent of the *London Times* for their failure to supply owner-driven cars with adequate body equipment and conveniences. Adjustable pedals, means for carrying the jack, tire pump, oil can, spare wheel, tools and other articles are things the owner driver wants, the correspondent declares. Adjustable individual footrests for rear passengers would add largely to their comfort.

Complaint is registered in the matter of floor boards made in such a way that grit and dust work through into the mechanism below and lack of handles of sensible design to remove them for oiling chassis parts. Floor boards that are screwed down afford little opportunity to

follow the instructions given to oil the clutch withdrawing mechanism and spigot bearing daily. Pocket, shelf and drawer accommodations are also pointed out as being lacking so far as convenience is concerned.

"Finally," writes the correspondent, "the craze which body builders have for constructing a car with a sporting line heads in most cases directly away from comfort. Seat backs are made too low for shoulder support, and although a semi-recumbent position can be comfortable for the driver, who is practically held in place by pedals and steering wheel, it is, in my opinion, more fatiguing for a passenger than the less sporting and more sitting posture. Appearance counts for a good deal but should be of secondary importance."

## The Railroad Strike and the Automotive Industry

**T**HE automotive industry will face a great responsibility and a great opportunity if the proposed rail strike takes place. It is sincerely to be hoped that some means will be found of averting a tie-up of railroad transportation. But if such means are not found, the responsibility for keeping open the main avenues of transportation, of supplying the public with necessities, and of keeping business from stagnation will rest largely upon the automotive industry.

The industry has emphasized the utility functions of automotive vehicles for some years past. If the railroad strike actually takes place, an opportunity will be given to prove these utility claims in a most practical manner. The problem will be chiefly one of organization and cooperation. There is no doubt of the ability of the nine million vehicles in this country to perform an effective service in this emergency. Every individual and every association of individuals

within the industry, however, will have to cooperate in organization and service if a first-class job is to be done.

The N. A. C. C. has already wired President Harding, offering the services of the automobile industry in the mobilization of motor transport if needed. Manufacturers, dealers, and owners operating together can perform an immense public service in this emergency—and incidentally give an intensely practical demonstration of the possibilities of motor transport.

## Profiting by Experience

**I**T would seem to be the most obvious action for every automotive manufacturer to take to make it a point to see that each series of vehicles turned out is free from difficulties which had developed in earlier models, at least so far as this is possible through care in design and manufacture. He has, or certainly should have and make available to his engineering and production departments, service records which show wherein faults or failures have developed. Yet it is not an uncommon thing for a car to display the same failings year after year. Even major faults are not always remedied, but minor troubles, due very often more to carelessness in production or assembly than to inherently faulty design, are frequently allowed to persist, with the result that sales resistance to that particular make of car increases. Much money must then be spent in overcoming this resistance which might far better have been spent in remedying the fault in the first instance.

A condition of this sort is due primarily either to indifference or more likely to failure to study the performance of the car at first hand and the conditions which the purchaser meets in its use. The engineering department frequently tests the cars which it designs, but too frequently these tests are made under more or less ideal conditions, over good roads and with a mechanic, who knows the car thoroughly, at hand to make any necessary adjustments, with the result that the engineer fails to experience personally the difficulties which the man who purchases the car later and has little knowledge of mechanical matters is sure to encounter. Some of these troubles are taken care of by the service station and should be regularly reported back to the engineering and production departments, but some of the less serious ones, which do not prevent operation of the car, are allowed to continue, in spite of the annoyance they cause the operator.

It would pay every car manufacturer to oblige his designing engineers as well as some responsible men in his production and assembly force to take new cars in precisely the same condition in which they are turned over to purchasers, and drive them for several thousand miles under rather severe road conditions, making sure that the men who drive the car effect all required repairs and adjustments themselves, preferably using for road repairs only those tools furnished with the car. First-hand experience of this kind is the best eye-opener known. It will

teach the engineer lessons in respect to accessibility and dependability, or the lack of these qualities, which are seldom appreciated until they have annoyed the purchaser to the point of exasperation, and it will instruct men responsible for production and assembly in the need for care and thoroughness as no talks by the executive or complaints from the service department can ever do.

The men on the factory staff too frequently lack perspective, are too close to their own job to appreciate the viewpoint of the consumer of their product.

## Exporting Possibilities

FROM the newspaper columns the information has been gleaned that an Irishman named William Fitzgerald, described as a literary man who has spent much time in America, has obtained a ten-year monopoly to run motor buses in Spain. Another news item chronicles the fact that the French are planning to establish an automobile route across the Sahara Desert and that experiments looking toward this end were about to be started with cars of the caterpillar type with a rubber band, invented by the engineer Hinsten.

Regarding the Spanish project. Just now there is no such motor bus transportation in Spain; in fact, local transportation there is almost non-existent. Mr. Fitzgerald has formed a company with a capital of about \$5,600,000 in which a large London engineering firm and the London Motor Bus Company are interested.

What is true in Spain is true in other countries regarding the lack of local transportation facilities. Those who deplore the lack of an export market at the present time might do well to look into this phase of the situation. These casual news items indicate that automotive products are being sold in foreign countries. Buses will be imported in Spain and they will probably be of British design. Sooner or later other countries will begin to import buses.

The Sahara Desert project, aside from offering an exporting opportunity, will open up an important avenue of trade. It will mean the establishment of traffic throughout the entire French African empire and this will be enormously important for the future development of that area.

## Applying "Pure" Science

ENGINEERING is sometimes said to consist in the practical application of "pure" science, but engineers are not always well-grounded in their knowledge of the fundamental laws of science, nor do they always make use of this knowledge when they are well informed regarding it. Cases in which certain scientific information has been put to good use are not hard to find, and one such application, involving the use of neon, one of the rarer gases in the earth's atmosphere, was described in the last issue of AUTOMOTIVE INDUSTRIES.

Another property of neon which we believe is not generally known has been used in certain research work and can, no doubt, be applied in the automotive

industry. A discharge between the electrodes of a tube filled with neon takes place with great rapidity, requiring, it is said, but a few millionths of a second. This fact can be made use of by employing such a tube in place of and more conveniently than a stroboscope to secure successive instantaneous views of an object, such as a valve, in motion too rapid to be followed by the eye. To make such observations of the parts of an engine, for example, the tube is set up in a darkened room in which the engine is to be run and is connected in a high-tension circuit in series with a commutator driven in timed relation to the engine and so arranged that contact can be made, by varying the timing lever position, at any desired point in the cycle of the engine. A flash of light will be given at this point, and the parts of the engine illuminated by this flash of light alone during this very short interval will appear to the eye of the observer to be at rest. It is thus possible to detect valve chatter, observe the position of rapidly moving chain links in reference to sprocket teeth, note the position of springs in relation to positively moved parts, etc.

Engineers can often make use of a knowledge of facts of this character gained in a study of physics, chemistry and other of the pure sciences, and should, so far as possible, make it a point to follow developments in these fields.

## Find Out First

SOMETIMES a manufacturer spends several thousand dollars in perfecting an idea in his own factory that has already worked out successfully in some other plant. If the results of the other man's experience had been known, those several thousand dollars, as well as a great deal of his employees' time, would have been saved. Worse still, the idea may have been found unsuccessful in the other factory and consequently it will prove so in his own.

Andrew Carnegie once said, "Never undertake anything new until your managers have had an opportunity to examine everything that has been done throughout the world in that department."

It is for just such purposes that the various Government bureaus are established in Washington, and more advantages can be gained from them than is commonly recognized. For example, the newly organized automotive section of the Bureau of Foreign and Domestic Commerce bids fair to give some very practical aid to the industry. Export statistics will be improved as to accuracy and detail, while practical aid will be given in solving specific business problems.

This and other Government bureaus stand ready to furnish reliable information concerning many things. The manufacturer can help himself and others by furnishing these bureaus with statistics and by making them real "idea exchanges." Such a policy would pay in the long run. The manufacturer who profits by another's experience saves time and money. Experience is a great teacher, but oftentimes the tuition is high. Before attempting a new experiment it is usually a good idea to determine whether or not it has been tried elsewhere.

# Few Cities Lose in October Sales

## Likely to Maintain September Showing

Reports from All Chief Distributing Points Reflect Better Business Conditions

NEW YORK, Oct. 17.—Notwithstanding general predictions that automotive sales for October would show a decided slump, business thus far this month has held up remarkably well and in the aggregate promises to equal the record for September. In some sections the total sales will exceed last month's, and in only a few districts has there been a decline thus far. In most distribution centers business is on about the same level as for the past six months. The variation up and down has been unprecedentedly slight.

A survey of actual selling conditions made by correspondents of AUTOMOTIVE INDUSTRIES in the leading distribution centers shows that the only cities in which sales for the first half of October have fallen below September are Des Moines, Los Angeles, Buffalo, Columbus, Atlanta, Youngstown and New Orleans. In none of them has there been a serious drop.

### Enclosed Cars Help

Even in Des Moines, where the falling off has been most severe, enclosed-car business in sight is expected to bolster up the month's record of sales. The decrease in business in Los Angeles is attributed to expectation of prospective purchasers that there will be additional price cuts early in the year.

Distribution centers which report a better business for October than September are Detroit, Denver, San Francisco, Dallas and Birmingham. A gratifying feature of the gain in San Francisco is that trucks are leading passenger cars in both the city and country districts. Truck sales up to Oct. 12 equalled those for all of the month of September.

Better business in the Dallas territory is attributed to higher prices for farm commodities. The same is true in the Birmingham section.

Cities in which sales are holding their own as compared with September include New York, Milwaukee, Indianapolis, Minneapolis, Chicago, St. Louis and Topeka.

Reports from all districts reflect improvement in the general business conditions.

## HOW RETAIL SALES RUN IN CENTERS OF TRADE

The following table shows at a glance how retail sales of automobiles are running in the chief distribution centers this month as compared with September:

They are better in Detroit, San Francisco, Denver, Dallas, Kansas City and Birmingham.

They are running even in New York, Milwaukee, Indianapolis, Minneapolis, Chicago, St. Louis and Topeka.

They have fallen off slightly in Des Moines, Los Angeles, New Orleans, Columbus, Buffalo, Atlanta and Youngstown.

The market almost everywhere is glutted with used cars and this has a tendency to slow up sales of new vehicles. The consequence may be a curtailment of factory production later in the year.

The outlook for sales in enclosed cars is decidedly gratifying and deliveries in some lines may be delayed because of inability of car manufacturers to obtain bodies.

### Used Cars Felt in New York

NEW YORK, Oct. 17.—The metropolitan territory is just about holding its own in October sales, as compared with the September record. Lines which have new models to offer have had a noticeable spurt in orders, although few deliveries are yet on the books. Some other lines are running a little below September so far this month, in the city, while in the outlying counties the general trend is ahead of last month.

The hysterical situation as regards used car values, caused by recent declines in new car prices and by sacrifice offerings of dealers who have made long trades, is having a retarding effect on new car sales.

### Falling Off in Portland

PORTLAND, ORE., Oct. 17.—Retail sales of automobiles throughout the Portland district thus far in October have shown a falling off of approximately 25 per cent over the similar period in September. Ford, Chevrolet, Dodge and Buick continue a fair business, but other lines are quite inactive. During the first several days of October there was a flurry of buying due to the fact that purchasers got another split in license fee at that time. Many late September buyers held off until Oct. 1 to get advantage of this lower license rate. This spurt did not last, however.

## Trucks Lead Cars in San Francisco

Large Industrial Companies Are Making Purchases for Their Own Use

SAN FRANCISCO, Oct. 17.—October retail automotive business shows a slight but steady increase over September with trucks leading passenger cars in both city and country. Truck sales in this district up to Oct. 12 equalled those for all of September. Country business in passenger cars is improving because of the strengthening of prices the farmers and jobbers are getting for fruit and the sudden great increase in sales of grain to European buyers.

In the cities, cars with new models and substantial price cuts show a stimulated business and standard makes, especially of popular priced cars, are doing what the dealers consider a nice business. Old models are stagnant owing to the anticipation on the part of the public that all lines will present new models at the New York show.

Trucks are making so much better a showing because of the purchase by large industrial companies of fleets for their own use rather than for contract hauling or for regular freight schedules. People and firms who need trucks seem to be realizing that the journey to normalcy is nearly over and that they might as well buy now and get to work with the trucks as delay buying and so hinder the return of business to normal conditions.

### Kansas City Goes Ahead

KANSAS CITY, Oct. 17.—October sales of new cars are running ahead of September sales. If the present rate keeps up, October will show a gain of about 20 per cent over September. The sales of new cars are running more than this proportion ahead of last month, but the movement of used cars has declined. This refers to local retail trade; the wholesale distribution is slowing. Sales are keeping up with the volume of October of 1920.

### Dallas Improves

DALLAS, Oct. 17.—Retail sales of automobiles, tires and accessories for the first half of October exceeded those for the first half of September. Dealers say this is due to reduction in the prices of cars and an increase in the price of farm commodities. The increase in the Dallas territory is about 10 per cent and in the Houston territory about 15 per cent. The outlook for the remainder of the year is bright, retailers declare.

# Nation Turns Eyes to Motor Trucks

## Vehicles Would Meet Looming R. R. Strike

Entire Automotive Industry Offers Its Services Through N. A. C. C.

NEW YORK, Oct. 18—Menace of a general railroad strike which threatens practical paralysis of rail transportation, has centered the attention of the nation upon motor vehicles.

Motor trucks never have failed in an emergency. They saved France in the great war; they kept business moving during the "outlaw" railroad strike. They will be mobilized to feed the nation if the railroads cease to function.

In the last great railroad strike the country was helpless for motor transport was unknown. It is significant that when announcement of the general strike call was made by the Brotherhood leaders Sunday, there were few gasps of apprehension.

Mayors of cities from one end of the country to the other countered immediately with the statement that their people would be fed by the mobilization of huge fleets of trucks to bring in and distribute food.

If no trains are run the mails will be transported by motor trucks and airplane.

Industrial paralysis will not follow a general strike because many factories can be kept in operation by the use of trucks to haul supplies and finished products.

Motor trucks figure prominently in the plans of the administration for meeting a strike. The War, Navy and Agriculture Departments are surveying the field to determine the number of trucks which can be mobilized. The same procedure is being followed by many states and by countless cities.

### 57,000 Trucks in New York

More than 57,000 motor trucks are available in the five boroughs of New York to transport food and other necessities in the event of a strike. It is estimated they could transport 28,000,000 lbs. of food a day if it could be obtained within a day's journey of the city.

The United States Army has about 200 3½-ton trucks in the city and the Navy about half that number. Only about half these trucks are being used by the Government and the others will be available in an emergency.

## READY FOR EMERGENCY, REEVES TELLS HARDING

NEW YORK, Oct. 17—Alfred Reeves, general manager of the National Automobile Chamber of Commerce, sent the following telegram to President Harding at the White House to-day.

"Cars and trucks totalling 9,200,000 can protect public in event of rail strike.

"We offer service of automobile industry in mobilizing of motor transport if needed.

"Local automobile owner and dealer associations have the organization, man-power and vision for emergency."

A special meeting of the Motor Truck Association has been called to gather data necessary for the immediate mobilization of motor equipment. Similar information is being collected by Health Commissioner Copeland, who will have charge of the rationing of the city in an emergency.

### Arranging Food Transportation

If there is danger of an actual food shortage it is probable officers of the Motor Transport Service of the Army may be asked to take charge of the service under plans which were worked out in 1919. The distribution of food by the Motor Corps, which will be mobilized, will be under the direction of the Health Department.

No decision has been reached by the American Railway Express Co. and other owners of large fleets of trucks as to what disposition they will make of their vehicles if the railroads cease to function.

Motion picture interests are making arrangements to distribute films by truck if it becomes impossible to move them by express.

### Could Meet Emergency

The 990,000 motor trucks in use in the United States hauled 1,200,000 tons of freight in 1920, or half as much as the railroads carried. These vehicles can readily handle the more essential products in case of a strike.

There are 3,000,000 motor vehicles in use on the farms of the country, including 139,000 trucks. If the motor vehicles in any large community were mobilized for the emergency, they could readily handle the suburban and inter-urban passenger traffic which ordinarily goes to the railroads. This is true even in great centers like New York and Chicago.

## Government Makes Mobilization Survey

Proposed Method: Would Force Allocation to All Centers of Population

WASHINGTON, Oct. 18—Mobilization of motor vehicles under governmental auspices has again established the essentiality of motor trucks. Government officials frankly admit their dependence upon this mode of transportation to stave off the effects of a railroad strike which is regarded as almost a certainty.

Survey of motorized equipment owned or controlled by the Government has been ordered by the Secretary of War. Plans drafted by the Council of National Defense to meet transportation emergencies are being studied with a view to revision to meet changed conditions.

### Ascertaining Location

As the crisis develops all agencies, private and governmental, are inquiring into the number of trucks and other motor vehicles available and their location. There has been some talk of creating as an emergency position a Director of Traffic who would co-operate with various governmental agencies in getting motor vehicles to strategic points.

This method would force allocation of trucks to centers of population. However, no definite plans have been made up to this time as governmental agencies are using all influence to bring about an amicable adjustment of the differences between the railroad operators and workers.

### Army Has 31,529

Statistics furnished AUTOMOTIVE INDUSTRIES to-day show that the War Department has available 31,529 motor vehicles of all sorts which are serviceable. These machines are located at army depots, posts and warehouses throughout the country and could be sent to various cities whenever desired. These machines would be operated by the army personnel and it is possible that some would be turned over to the Post Office Department for transportation of mails and foodstuffs.

Inquiry shows that the Bureau of Public Roads has 1197 trucks, 215 automobiles and 27 ambulances in service throughout the country. Other statistics show that 21,124 trucks have been delivered to various State highway organizations out of a total allotment of 27,983 vehicles.

The Bureau of Public Roads says that highway transport was never in better position to meet demands for transport-

(Continued on page 797)

## Peerless Anticipates Capacity Production

Goal Set by Collins Would Mean Output of 10,000 Cars Yearly

CLEVELAND, Oct. 17—Capacity production for the Peerless Motor Car Co. within a comparatively short time is the goal set by R. H. Collins, new president and general manager.

This means the turning out of cars at the rate of 10,000 per year. At the present time the output is about 10 cars a day or at the rate of about 3500 cars a year. Last year the plant turned out 6000 cars.

These figures indicate that Collins has a man's sized job on his hands. But there have been developments which have caused men in the financial district here to believe that the goal will be reached and at no distant period.

With the vigor and intelligence that marked his connection with Cadillac, Collins has gone about his task as president and general manager of Peerless. While the ink on the contract for the sale of the plant was wet, he had plans already under way for the development and expansion of the business.

Some of his confidential advisers have been on the job at Peerless for some time. These experts have been in conference with W. H. Staring, production manager, and other officials of Peerless. B. H. Anibal, former chief engineer of the Cadillac company, and a body engineer who is nationally known are two men who have been representing Collins in what has been going on at the Peerless plant since the purchase of the controlling interest.

Collins would not discuss his plans before he left the city for a short trip to the West. It is said, however, changes will be made in methods in the company's sales organization, and that gaps in the organization will be filled. No changes in the personnel are contemplated at present.

The old officials left Collins a rich heritage in the form of financial stability. Cash and securities on hand aggregate a value of \$4,000,000, while the quick assets total \$8,000,000. The outstanding bills amount to but \$400,000.

## Body Builder Buys Moore Motors Plant

DANVILLE, ILL., Oct. 17—Idle since the failure of two years ago, the plant of the Moore Motor Co. here has been purchased by the L. C. Graves Co., a corporation of Springboro, Pa., manufacturer of commercial car and truck bodies, and will be operated under the name of the United Automotive Body Co., employing approximately 500 men. The new company will be capitalized for \$1,250,000.

The United Automotive Body Co. of Cleveland was recently absorbed by the

## KEEP DOORS CLOSED ON JACKSON MERGER

NEW YORK, Oct. 19—Close secrecy still shrouds the proposed merger of 14 automotive companies in which the Jackson Motors Corp. and the Traffic Truck Co. will be included. It is believed, however, that the various companies will be taken over by the Associated Motor Industries, which has been incorporated in Delaware with a capital of \$80,000,000.

Every effort has been made to prevent information concerning this corporation from becoming public. The papers were filed by the Corporation Trust Co. of America, which is located in Wilmington. The incorporators of record are attachés of the trust company.

No clues are contained in the incorporation papers and the Wilmington company declines to reveal even the name of the attorney or where the offices outside of Delaware are located.

L. C. Graves Corp. The latter was organized in 1870 for the manufacture of horse propelled vehicles. F. O. Darling is general manager and R. M. Hawn chief engineer of the Graves company. The former will make his headquarters here.

The Cleveland office is to be closed, but branches at Detroit, Lansing, Toledo and Youngstown will be continued.

## Associate President of Lafayette Resigns

INDIANAPOLIS, Oct. 17—Charles W. Nash, president of the Lafayette Motors Co., announces that he has accepted the resignation of D. McCall White as associate president of the Lafayette company. White feels that the corporation has reached a point in its development of the Lafayette car where his services as a designing engineer are no longer required. Management of the company will not be affected in any way and no successor to White will be appointed.

## Dunlop Stock Falls with Dividend Passing

LONDON, Oct. 15 (By Cable)—The Dunlop Rubber Co., Ltd., has passed its dividend on £5,000,000 of preference stock because of the depreciated value of rubber and cotton supplies on hand. This decision seriously affects the prospects for a dividend on the parent tire stock.

The announcement resulted in further depreciation of all classes of Dunlop stock. Some critics regard the passing of the dividends as a conservative policy but others recall that the company issued 3,000,000 pounds sterling of 8 per cent debenture stock to straighten out its financial difficulties only a few months ago.

## Ford May Purchase Another Railroad

Secures Option on Line Which Will Give D. T. I. Entrance to Cincinnati

CINCINNATI, Oct. 17—The following copyrighted dispatch bearing a Cincinnati date line has been sent out by the United Press:

Possibility of a Henry Ford railroad extending from Detroit to Cincinnati was intimated in Ford's exclusive statement to the United Press that he had secured an option on the Cincinnati, Milford & Blanchester, which gives his Detroit, Toledo & Ironton an entrance to Cincinnati.

B. H. Kroger, one of the principal owners of the C. M. & B. traction line, announced that Ford held an option on the road.

Although his party is not concerning itself with negotiations for purchase of other lines, Ford announced that his secretary was to consult with officials of the Cincinnati, Milford & Blanchester Traction Line.

"If the figure is right I have told my secretary to notify officials of the road that I would be interested," he said. The road would be converted into a branch of the Detroit, Toledo & Ironton Railroad.

"If the Government will let me have Muscle Shoals I'll teach it something about solving unemployment problems," he stated further.

Ford would not go into details about his plan.

"There are jobs in this country for every man who wants to work," he said. "The solution of all this trouble is simple after it has been explained, but it is too long a story to tell now. We have shown this country something about employing men, but that is only a start to what we can do if we get Muscle Shoals."

The Muscle Shoals plant was established by the Government during the war for manufacture of nitrates. Ford offered to take over the establishment to manufacture fertilizer, but his offer has not been accepted.

## Kansas City Bringing Delinquents to Court

KANSAS CITY, Oct. 18—The number of suits on account being filed in the county circuit courts, indicates that merchants are going after delinquent customers most aggressively. Among the suits are numerous ones for the recovery of motor cars or trucks, sold on time, or on which petitioners hold notes.

It is evident, without the direct testimony of merchants, that "patience has ceased to be a virtue," and that they have carried the delinquents as long as they care to.

Among the suits are noted several against garages.

## Business Reviving, Truck Sales Show

### Better Country-Wide Conditions Indicated by Increasing Need for Transportation

NEW YORK, Oct. 17—Steadily increasing sales of motor trucks of all capacities have tended to arouse an even greater feeling of confidence in the automotive industry than the surprising way in which passenger car sales have held up. The demand for motor trucks fell off in direct proportion to the general business depression and the fact that many more trucks are being purchased demonstrates conclusively that business as a whole is coming back.

#### Freight Cars Move

When there were no goods to be moved there was no need for trucks but with the general expansion in manufacturing and the increasing need for transportation, trucks have come into their own again as the best means of handling short haul business. Truck sales have risen steadily as the number of idle freight cars on the railroads has decreased, showing the close relation between rail and highway freight traffic.

Sales by approximately 60 of the leading truck companies for the second quarter show an increase over the first quarter of more than 5000 or nearly 40 per cent. In many cases companies reported an increase of 100 per cent in sales. This was particularly true in the case of those specializing in heavier vehicles. The Dodge truck business for the second quarter increased 500 per cent over the first quarter. When production figures for the third quarter are available they will show, in general, fully as great a gain over the second quarter.

#### Heavier Types in Demand

Among manufacturers of the heavier types of truck International Motors and the White Co. are leading their competitors by a considerable margin. The former, which has been doing a satisfactory business all through the year, delivered more trucks in September than in any month since June and for the first 10 days of October took twice as many orders as for the same period in September. The White company has shown a steadily increasing business each month since May. The Packard company reports deliveries of commercial vehicles in the Metropolitan district 50 per cent larger in September than in August and that the present month promises to be equally good.

Pierce-Arrow also is doing a much better truck business. The Autocar Co., which had an increase of 100 per cent in the second quarter over the first quarter, reports that while July and August were comparatively dull there was a marked increase in demand in September and that October promises to be the best month of the year.

While there almost always is a sea-

### TWO TIRE PRICES CUT; MAY BE GENERAL MOVE

AKRON, Oct. 18—The Miller Rubber Co. announces to-day a 15 per cent reduction in price on the two most popular sizes of its fabric non-skid automobile tires. This is accepted in Akron as the beginning of another general tire price cut, although no other Akron company will admit that it contemplates reductions. The Miller reductions cover the 30 x 3½ and the 30 x 3 sizes.

KENT, OHIO, Oct. 18—D. M. Mason, general manager of the Mason Rubber Co., announces a 15 per cent price reduction on cord tires, effective at once. He states that the cut is made possible by capacity production and "absolute freedom from high cost inventories."

sonal slump in the sale of passenger cars in the winter months, truck business does not fall off to such a great extent and it is probable that manufacturers of commercial vehicles will be able to make a very satisfactory showing on the year's business.

### Forming Shaw Motors to Produce \$700 Car

DETROIT, Oct. 17—Shaw Bros. Motor Car Co. is being organized in this city for the manufacture of a four-cylinder car which will sell for between \$700 and \$800. The car will be conventional in its type, but will embody several new construction features which will be patented and limited to exclusive Shaw use.

The car will be known as the Shaw Bros. or Shaw, the name not being fully determined. It has been designed by E. R. De Luiz, formerly an engineer on the Ford staff, and experimental models are nearing completion. E. P. Telotte, former Buick representative in this city, has been named sales manager of the company.

The Shaw brothers, William and Roy G., who are heading the new company, are well known in Detroit automotive and financial circles. Roy G. Shaw was formerly a factory executive at the Ford plant, while William Shaw has been connected with Buick in sales capacities. The company will be capitalized at about \$3,000,000. The first cars will be exhibited at show time.

### Set Definite Dates for Argentine Show

BUENOS AIRES, Sept. 19 (By Mail)—The dates of the fourth automobile exposition of the Automovil Club Argentino, in the Pabellon de las Rosas, have been fixed as Nov. 12 to 27.

## Straight Side Tire Campaign Started

### Rubber Association Will Distribute Booklets Extolling Advantages Over Clincher Type

WASHINGTON, Oct. 17—More than 50,000 booklets extolling the advantages of the straight side over the clincher type of tires will be distributed in various countries by the Rubber Association of America in its work of developing world sales on American-made tires. This booklet is now being put on the press, its translation into several languages having been finished. An effort will be made to circulate the first copies in England before the close of the Olympia show in November.

The straight side campaign is the work of P. L. Palmerton, who recently resigned as foreign trade secretary for the association to become chief of the rubber division of the Bureau of Foreign and Domestic Commerce. Palmerton is the author of the booklet now coming off the press and its distribution will be under his supervision, this work having been retained by him when he left the association.

The records in Palmerton's office show that the straight side is continuing to gain popularity throughout the automotive markets of the world. This also is true of cord tires larger than Ford sizes. Practically 25 per cent of all tires exported in August were of cord construction, and nearly four-fifths when the Ford sizes are eliminated. Sales of cords in the Ford sizes are growing in the foreign field, but the percentage is still small, fabrics dominating this branch of the business.

### Favor Reorganization of Texas Motor Car

FORT WORTH, Oct. 17—Group meetings are being held wherever in the Southwest enough stockholders live to vote on assessing shares for reopening the Texas Motor Car Association. Thus far, the meetings have resulted in approval of the assessment. Two hundred stockholders have given their assent to the plan.

It was announced accordingly by Chairman L. W. Hilbrun of the assessment committee that reorganization would be started immediately in the affairs of the company and the factories in South Fort Worth will resume operation. At present, the company is in the hands of two receivers who are operating only the body works and repair shops. Production was discontinued last fall.

The group meetings will continue all this month, or until every stockholder has been given an opportunity to vote for or against the assessment. The stockholders are being assessed 25 per cent of their original stock in the company. Many have paid in the actual cash.

## Ricardo Will Read Paper Before S. A. E.

Program of Society for Winter  
Season Will Include Three  
Meetings

NEW YORK, Oct. 18—The winter meetings of the Society of Automotive Engineers will include the annual meeting in New York, Jan. 11-14; a meeting in Chicago on Feb. 1 and a tractor meeting in Minneapolis, Feb. 8.

Harry R. Ricardo of London has accepted the society's invitation to present one of the principal papers for the annual meeting. This will deal with his automotive research work, some records of which have appeared from time to time in AUTOMOTIVE INDUSTRIES.

Among the reports to be submitted to the standards committee is that of the Iron and Steel Division, revising and bringing up to date the present S. A. E. steel specifications. H. M. Crane, chairman of the research committee, and Dr. H. C. Dickinson, manager of the new research department, will also submit reports.

Among other papers to be read at the annual meeting are the following:

Air-cooled Engines, by Charles Lawrence; Car Upholstery, by R. F. Quaintance; Body Seating Dimensions, by George E. Goddard; Manufacture and Application of Paints and Varnishes, by L. V. Pulsifer; California Tops, by Paul W. Steinbeck. Papers on lubrication will be presented by Dr. Herschel of the Bureau of Standards, Prof. R. E. Wilson of Massachusetts Institute of Technology and Nell MacCull of the Texas Co. The Fuel Session will include papers on Spectroscopic Studies of Combustion by Thomas Midgely, Jr., and W. K. Gilkie; Evaporation of Engine Fuels by O. C. Berry and Measuring detonation by T. A. Boyd. The Bureau of Standards will co-operate in providing material for this session.

The Material Session will include papers on Aluminum Alloys by Zay Jeffries, Malleable Iron by Enrique Touceda, Rolled Forgings by G. R. Norton. Papers on drop forging practice and alloy steels are expected.

The Passenger Car Session will be devoted largely to discussion of brakes, with a paper on this subject by J. Edward Schipper, and one by S. Von Ammon on Brake Lining Tests at the Bureau of Standards.

The meetings in New York, Chicago and Minneapolis will include the usual dinners.

## Motor Vehicle Value Told to Hardware Men

ATLANTIC CITY, Oct. 20—Alfred Reeves, general manager of the National Automobile Chamber of Commerce, in an address to-day before the annual convention of the National Hardware Association declared that "a few years more will see America on wheels, with millions of motor cars and trucks co-ordinating their service with the railways, waterways and trolleys."

## MEN REPLACE WOMEN AT REMY FACTORY

ANDERSON, IND., Oct. 18—Announcement has been officially made at the Remy Electric Co. plant that its contribution to the nation-wide effort to relieve unemployment would be the placing of men in positions now held by women, particularly in the cases where married women are concerned.

Five women in one department also have husbands employed by the factory. It is understood that these will be the first women to go. World War veterans, it is planned, will be given preference in filling places of women, although the announced policy of the company is that married men first will be employed.

"Our people demand the best form of transportation, and the motor vehicle, whether for merchandise, for bus lines or for individual service, will on meritorious performance secure its share of patronage, with the proper share going to the railroads, trolleys and waterways," Reeves said. "Each has its place and each can be helpful by increasing the efficiency of the nation."

## Mitchell Producing New 6-Cylinder Engine

CHICAGO, Oct. 17—W. L. Jacoby, president of Mitchell Motors Co., Inc., entertained 75 of his distributors at a dinner at the Blackstone Hotel here to announce to them the production of a new six cylinder engine. The following day the whole party was taken to the factory at Racine, Wis., to see demonstrations of the new product.

Speed and hill climbing tests were given and it is said that the characteristics of the new engine stood out prominently in these tests. The engine is known as the F-50 and the features of it, as claimed by the Mitchell engineers, are greater fuel economy and flexibility. The distributors were enthusiastic over the performance of the new product and reciprocated with orders that will enable the Mitchell plant to increase its production schedule for some months ahead.

## Goodyear Sales Exceed Business of Year Ago

AKRON, Oct. 17—As a striking instance of the distance the rubber industry had swung back toward normal, Edward G. Wilmer, president of the Goodyear Tire & Rubber Co., states that notwithstanding the fact that sales during the first six months of 1920 had exceeded those of any period in the company's history, more tires had been sold during the 10 months up to Oct. 1, 1921, than in the same period a year ago. In September the company sold 69,000 more tires than in September a year ago, Wilmer says.

## Runabout Brings Rover Big Profit

British Company Is Proposing to  
Distribute Dividend of  
10 Per Cent

LONDON, Sept. 30 (By Mail)—Profit of the Rover Co., Coventry, for the year was \$511,595 compared with \$655,000 in 1919-20 and \$720,340 in 1918-19. It is proposed to pay a dividend of 10 per cent, put \$50,000 to the reserve, write \$50,000 off the cost of the employees' canteen and sports club and carry forward \$168,740 as against \$132,140 brought in.

This company has paid several very large dividends in the past but in October, 1919, the shares were doubled by a bonus distribution, and the dividend, which just before had been 25 per cent was reduced last year to 10 per cent free of tax.

Most of the year's success is attributed to the air-cooled two cylinder light runabout which has had an output nearing 200 a week for some time. The company's other model, a "12" of conventional type, has suffered by this change in demand, but it is fairly certain that as soon as manufacturing costs fall enough to cut the sales price discrepancy, which is about 100 per cent between the two cars, the more expensive model will regain its pre-war favor.

The likely advent of similar light cars announced by the Wolseley, Belsize and others indicates that competition will be intensive in this class of car which must militate against the Rover company's chances of earning the big profit just announced. The Rover company, however, is more fortunate than some of its competitors in the line in having the capital to finance the purchase of material at lowest rates, and in having but one stable type, as compared with the three or even five models of some other companies entering the air-cooled light car market.

## Madison Tire Adopts Expansion Program

BUFFALO, Oct. 17—A general expansion program has just been inaugurated by the Madison Tire & Rubber Co. of Buffalo.

The officials state that their finances are in excellent shape and that the expansion of their distributors' organization is based on the substantial financial condition of the company.

J. M. Dine, general sales manager, recently with the Oldfield company, has been elected vice-president in charge of sales. Frank H. Brewster, who has been with the company as superintendent for 20 years, has been elected vice-president in charge of production. Charles B. Brewster, whose services with Madison date back to 1913, has been elected assistant treasurer. Fred Griscomb is the chief engineer.

## 3,000,000 Tires Liquidated in Year

**More Than \$50,000,000 Has Been  
Released by Akron  
Manufacturers**

AKRON, Oct. 17.—The extent to which Akron rubber tire manufacturing companies have readjusted inventories and have re-established themselves on a substantially sound basis of operation both from the standpoint of available working capital and from the viewpoint of potential sales, is revealed by announcement of the fact that since Jan. 1 approximately 3,000,000 tires have been liquidated out of finished goods inventories.

This estimate is conservative according to officials of the B. F. Goodrich Co., who state that an actual survey of inventory readjustments of Akron companies, both in Akron and in warehouses scattered throughout the country, no doubt would show a much heavier tire liquidation. Goodrich alone since Jan. 1 has reduced its finished goods inventory by more than one million tire units.

### More Capital Available

This heavy liquidation of tires has meant the release of between \$50,000,000 and \$75,000,000 in working capital with which to re-establish the tire industry on a sound basis, according to W. A. Johnson, Goodrich automobile tire sales manager.

This fact is significant from several viewpoints.

First, the release of more than \$50,000,000 in working capital makes available finances with which to now expand finished goods inventories and also provides working capital with which to lay plans for a substantial spurt in the tire industry next year.

Second, the heavy liquidation of tires means not alone increased production, but the re-employment of perhaps thousands of men before Jan. 1 in Akron tire factories.

### No Low Ebb Production

So far this year, for every tire built from two to three tires have been sold. With inventories down to a basis of rock bottom and as low as they perhaps ever will be in the history of the industry, all major tire companies are in a position to expand inventories. From now on until such time as inventory expansion is definitely undertaken, the present status of the industry in Akron means that for every tire sold a tire must be built.

Johnson emphatically disputes the generally accepted belief that Akron and the tire industry face another disastrous winter of low-ebb production, straitened financial circumstances for the major companies, and heavy unemployment of men. He cites the present status of the tire industry on a basis of inventory liquidation, to corroborate his contention that by Jan. 1 the tire industry will be back to normal and that soon

## 1251 SUGGESTIONS MADE IN FRANKLIN CONTEST

SYRACUSE, Oct. 17.—The Franklin Automobile Co. has distributed \$3,600 in prizes among its employees as a result of the "suggestion system" put into effect last March. The plan was adopted to cut down the cost of production without lowering the quality of the car. In all, 1251 suggestions were submitted during the first six months and of this number 503 were adopted. There were two first prizes of \$400, two of \$300, three of \$200 and two of \$100. The rest graded down to \$10 each.

after the first of the year the industry will be normal with a plus sign after the word.

One tremendously significant point brought out by Johnson is the fact that the number of tires now constituting finished goods inventories is less to-day than the number of tires Akron companies were forced to keep in transit a year and two years ago.

Another significant statement made by him is to the effect that even in the face of one of the worst industrial depressions recorded in the history of America, the automotive industry, of which the tire industry is part, has made progress.

## Changes in Directorate Made by Fisk Rubber

NEW YORK, Oct. 18.—The Fisk Rubber Co. has made changes in the personnel of its directorate following the financing recently arranged by local bankers. The board has been increased from seven to nine members. The new directors are William F. Cutler, James Dean, Richard S. Russell and Ralph H. Bollard. The resignation of J. D. Anderson, F. T. Ley and G. A. Ludington were accepted. H. G. Fisk, formerly treasurer, has resigned to become vice president.

The treasury department will be centered in New York as a result of the change in policy of transferring the executive departments of the Fisk, Federal and Ninigret companies, under the recent readjustment, to this city.

## 97,651 Cars and Trucks, Ford September Output

DETROIT, Oct. 18.—Ford Motor Co. announces final compilations for September production of domestic and foreign plants was 97,651 passenger cars and trucks. Of this 2,937 were made in Canada and 4,525 at other foreign plants. In addition, 827 tractors were turned out.

All Ford assembling plants are in operation. September output at Detroit of 7,408 vehicles was highest. Kearny was second with 7,036, followed by Chicago with 6,000 and St. Louis with 5,525. October schedules call for total output of 90,000 cars.

## Makers Announce New British Cars

**Armstrong Siddeley, Wolseley and  
Austin Among Firms Describ-  
ing Late Models**

LONDON, Oct. 3 (*By Mail*)—A number of British manufacturers are permitting announcements concerning their new models and programs to appear much more in advance of the Olympia show than has hitherto been the case.

The new 18 hp. six-cylinder Armstrong Siddeley (2½ x 4½ in.) proves to be merely a smaller rendering of the 30 hp. six-cylinder chassis, which it will supplement and not displace. Another and still smaller new model is also in preparation by the same maker, but this will be on quite different lines.

### Armstrong Siddeley

The 18 hp. has valves in the integral heads of the cast iron cylinders (the latter formed in threes), push-rod operation and full pressure lubrication. Magneto ignition is continued and also the other main features of the "thirty," that is, dry multi-plate clutch, gearset as unit with front end of torque tube, helical bevel drive, disk wheels, with steering pivots vertical and central, and Marmon type frame and footboards. It will sell at £795 with four-passenger body.

The new light Wolseley, a 7 hp. two-cylinder, water-cooled runabout, will supplement the three existing models, viz. 10 hp. and 15 hp. fours and 20 hp. six. It will be more expensive, though probably better finished externally, than the 8 hp. aircooled Rover, which will be one of its chief competitors, for the selling price will probably be £300.

### Austin's Late Model

Austin's new model is a 12 hp., four-cylinder (2½ x 4 in.), and this also is much on the same lines as the 20 hp. four, which is to be continued. It has a detachable L head engine, magneto ignition, single plate clutch, four-speed gearset and spiral bevel drive, and with a small four-passenger body will be sold at about £550, which compares with £695 for the "twenty."

Although several firms, Rover, Hummer, Daimler and others, have recently made definite announcements as to reductions and prices for the whole of 1922, it appears to be not at all unlikely that they may after all be modified again before the show. The price of the Armstrong Siddeley is causing a flutter and there are other firms still to make their 1922 figures known.

### DRIGGS STARTS PRODUCTION

NEW HAVEN, Oct. 15.—The Driggs Mfg. Co., which was formed some time ago to build a line of passenger cars, has completed the test car and a first lot of twenty-five cars is being put through for production.

## CITIES MAINTAIN SALES PACE IN OCTOBER

### Drives Help Chicago

CHICAGO, Oct. 17—Under strong sales drives, Chicago business so far in October compares favorably with September, except for Buick's report of a 25 per cent decrease. Dodge is exactly even, Studebaker even, Nash shows a slight decrease, Mitchell a decrease in the country, Cadillac is even, Pierce-Arrow below normal but equal to September. Other lines place business on the September level.

### No Gain in Minneapolis

MINNEAPOLIS, Oct. 17—Broadly speaking, the retail situation shows no gain over September. However, the Ninth Federal Reserve Bank here now owes no outside banks as against \$24,000,000 in November last year. The re-discount rate has just dropped a half cent, the last of the reserve banks to come down. This liquidation and lower rate is expected to be reflected in the motor trade but perhaps not this fall. There is a feeling that price reductions are not over and, therefore, that this is no time to buy. Outside dealers have not been able to borrow adequately on car shipments.

### Good Columbus Demand

COLUMBUS, Oct. 17—Despite the fact that the season for the sale of passenger cars is waning, Columbus dealers have been having a fairly good demand. This is especially true of the lower and medium priced lines. Cars averaging between \$800 and \$2,200 have been selling rather briskly when industrial conditions are taken into consideration. The tone of the trade shows a distinct improvement and more optimism has developed among the dealers.

### New Orleans Behind

NEW ORLEANS, Oct. 17—New Orleans automobile dealers report business for the first part of October, while holding up fairly well, is somewhat slack as compared with September. This applies more particularly to used cars, which problem the local dealers have so far failed to solve. Part of the slowing up is attributed to the general moving which occurs about this time of year.

### Slowing Down in Buffalo

BUFFALO, Oct. 17—Sales of new cars here have slowed down considerably since the beginning of September, although there are a few exceptions among the dealers who report that business is good. All the dealers believe, however, that by next spring conditions will be entirely satisfactory.

It is the used car problem which is giving the Buffalo dealers the greatest concern, for this market has become very sluggish although all sorts of expedients have been adopted to increase sales. The Buffalo Automobile Dealers' Association

has decided to hold its annual show in January instead of in March as has been the custom, in the hope of stimulating sales.

### Slackening in Des Moines

DES MOINES, IOWA, Oct. 17—With one or two exceptions, the leading dealers of Des Moines report a material falling off in October retail business as compared with September. Percentages of decreases vary from 30 to 50. One dealer reports a slight improvement and another no change. Ford business is 10 per cent under September. Some good enclosed car business is in sight and is expected to bolster up business the latter part of the month.

### Increase in Birmingham

BIRMINGHAM, Oct. 17—With more money in circulation and the Alabama State Fair ushering in October, retail automobile sales for the first half of the month are about 10 per cent higher than for the same period in September. The semi-centennial celebration and the automobile show are expected by conservative dealers to bring them 25 per cent over last month's sales. Fords continue to lead with an average of 15 cars daily compared with 11 in September. Other makes show about the same proportionate gain.

### Decline in Atlanta

ATLANTA, Oct. 17—Retail automobile sales in Georgia for the first half of October are estimated at about 50 per cent of sales for the first half of September. License receipts to Sept. 15 will more than double receipts to Oct. 15.

### Los Angeles Expects Cuts

LOS ANGELES, Oct. 17—October retail sales are running behind those of the corresponding period in September. The reason assigned by dealers is an anticipated price decline early in the year. The public responded strongly to early announcements of lower prices and subsequent advertising that cuts meant stabilization of the industry and that a further decline could not be expected. The most recent reductions apparently have destroyed buying confidence. There is practically no demand for used cars priced above \$1,000.

### Decrease in Youngstown

YOUNGSTOWN, Oct. 17—Sales of high priced cars have increased 10 per cent for the first half of October as compared with the first half of September. Sales of Fords and Dodges decreased 20 per cent. Cars in the intermediate class showed a decrease of 10 per cent and the general average was a decrease of 18 per cent in retail sales with little money available for down payments.

### Increase in Denver

DENVER, Oct. 17—Reports from leading dealers show October sales ranging from 65 per cent to 125 per cent of the first half of September. One dealer, whose sales were slightly below September, explains that the difference is due to a temporary shortage of enclosed models and expects the October total to be ahead while some predict the month will show a little less and others that it will prove equal or better.

### Indiana Spotty

INDIANAPOLIS, Oct. 17—Retail sales of automobiles continues even with September in the southern counties of Indiana. Northern counties generally are not so good while counties in the central part of the State are doing about the same amount of business in October as in September, with isolated spots showing an increase reflecting local industrial and business conditions. Indianapolis business is little changed from the latter part of September.

### Car Week Helps Detroit

DETROIT, Oct. 17—October business in Detroit will exceed September in all classes of cars. The increase has been helped along materially by the enclosed car week under the auspices of the dealers' association. The majority of dealers declare October already is surpassing September. The used car situation is the most serious deterrent to sales.

### Cuts Not Felt in St. Louis

ST. LOUIS, Oct. 17—October sales are on a par with September. Publicity on the show which opened Saturday has had a tendency to slacken sales for the past few days with the exception of a few popular makes. The used car market is flooded and the situation is getting serious. Price reductions are not increasing sales to any great extent.

### Running Even in Topeka

TOPEKA, Oct. 17—According to retailers, sales for the first half of October have been up to September's high record for the lower priced cars. In the class above \$1,000, however, a much slower pace is being maintained. The used car market has been fair, the output going mainly to farmers. Bankers of the State are assuming a more liberal policy toward automotive paper.

### Weather Affects Milwaukee

MILWAUKEE, Oct. 17—October retail sales generally are reported to be holding their own with September although some dealers find that the interest aroused by early September price reductions gradually disappeared in the last two or three weeks. The used car market is glutted. Sales have been slowed up by cold weather.

## Truck Operators Form Association

### Industries in Indiana Organize to Hold Conferences for Dis- cussing Needs

INDIANAPOLIS, Oct. 17—Believed to be the first organization of its kind, the Allied Motor Commerce, Inc., of Indiana, became a permanent organization here this week. Its constitution dedicates it to pursuits that can have an immensely valuable influence on the development of motor vehicle commerce.

The organization is not to replace any now in existence nor does it contemplate taking over the work of any of them. Its purpose is to provide a State conference of all industries using motor vehicles. Legislation, taxation, licensing and all regulatory matters will be primary interests. Through the central organization the full power of the motor commerce of the State can be brought to bear on every problem.

Membership in the conference must be by association, each group getting one delegate for every 100 trucks represented in the group membership. Each association must pay into the A. M. C. treasury \$1 per year per truck.

Interests represented in the permanent organization meeting were the Master Plumbers Association, Indianapolis Transfer Association, Indiana Transfer & Warehousemen's Association, Indiana Automotive Trade Association, Indiana Association of Electrical Contractors, Indianapolis Commercial Warehousemen, Indiana Highway Transport & Terminal Association, Indianapolis Coal Dealers Association, the Associated Cleaners & Dyers of Indiana, and the Indianapolis Sand & Gravel Association.

It is anticipated that by Jan. 1, 1922, the organization will have 17 Indiana State bodies affiliated, representing some 20,000 of the 45,000 motor trucks operating in Indiana.

### Complains Against Use of Franklin Tire Name

WASHINGTON, Oct. 18—Formal complaint by the Federal Trade Commission has been issued against A. S. Fox, trading under the name and style of Franklin Tire & Rubber Co., and L. Goodman. Fox, who has his headquarters at Chicago and a branch at Oklahoma City, Okla., is charged with simulating the name of a competitor, the Franklin Tire & Rubber Co. of Kent, Ohio, which is an Ohio corporation and a subsidiary of the Mason Tire & Rubber Co.

The complaint alleges that the Ohio firm through extensive advertising and quality of its products has become widely known to the trade, and that the use by A. S. Fox, as principal, and L. Goodman, as sales manager, in charge of a branch establishment, of the true corporate name has caused confusion in the trade and injury to the Ohio company.

## Exports of Automobiles, Airplanes, Trucks, Farm Tractors, Motorcycles and Parts for September and Eight Previous Months

	Month of Sept.				9 Months Ending Sept.			
	1920		1921		1920		1921

### New York Registered 4301 Cars Last Month

NEW YORK, Oct. 17—Registrations of new cars of '88 makes in 10 counties in and around New York City in September numbered 4301 as compared with 4575 in August and 7012 in June, the high month of the year.

The figures, compiled by Sherlock & Arnold, publishers of the Automobile Sales Analysis, show a drop of only 274 in September from the August total, which is less than a normal decline, as August usually has a spurt due to pre-Labor Day sales, while September ordinarily has a "dead" week immediately following this holiday, which brings so many people in from vacations and is given up to getting settled and back to work.

Registrations, which are equivalent to deliveries, in the 10 counties follow for the months of the year up to date:

	Approximately below \$2,500	Approximately above \$2,500	Total
January .....	483	146	629
February ....	1,409	210	1,619
March .....	3,396	488	3,884
April .....	4,811	575	5,382
May .....	5,468	584	6,052
June .....	6,522	490	7,012
July .....	5,457	386	5,843
August .....	4,216	350	4,566
September ..	3,986	315	4,301
<b>Total to date.</b>	<b>35,755</b>	<b>3,546</b>	<b>39,301</b>

### MAKING BUSES FOR AKRON

AKRON, OHIO, Oct. 17—The Northern Ohio Traction & Light Co. is constructing three 25 passenger buses, finished in style similar to the standard make of street car and shod with pneumatic tires and is planning to put them in operation at once on Akron streets not now traveled by street cars.

### Automotive Exports Show Distinct Gain

#### Striking Improvement Noted in Overseas Shipments of Parts and Trucks

WASHINGTON, Oct. 19—Automotive exports of passenger cars, motor trucks and parts, not including engines and tires, showed a distinct gain, when considered as a whole, during the month of September as compared with August. The monthly figures covering the foreign trade in these products, as announced to-day by the Bureau of Foreign and Domestic Commerce, showed a striking gain in the overseas shipments of parts and trucks whereas the passengers were practically at the same level as in the preceding month.

The comparative figures are as follows:

	Trucks		Cars		Parts
	No.	Value	No.	Value	Value
Sept. ..	472	\$481,664	2,197	\$1,870,770	\$2,570,860
Aug. ..	381	454,052	2,237	2,265,328	1,786,886

Other figures given in the monthly report showed that 627 motorcycles valued at \$151,380 were exported during the month as well as eight airplanes valued at \$31,000. To this should be added airplane parts worth an additional \$3,956. The total number of engines shipped during the month was 1210, with a value of \$302,533. Nearly one-half of these, or 539, were automobile engines, the majority of which, presumably, are for assembly into cars in other countries.

The report also shows that the sale of parts is continuing through this year at practically 50 per cent of last year's figures. For the first nine months of 1921, the value of parts shipped overseas was \$31,126,453. For the similar period of 1920, the value was \$62,426,871, tires not being included in either case.

## New Haven Railroad Orders Three Macks

### Rail Cars Will Be Used for Short Haul Passenger Traffic on Branches

NEW YORK, Oct. 18—The New York, New Haven & Hartford Railroad has placed an order with the International Motor Co. for three Model AC Mack rail cars which will be used to handle short haul passenger traffic on branch lines. This is taken as an indication of the interest being manifested by even the large trunk lines in automotive transportation as applied to railroad use.

The much greater economy of operation of motor-driven rail cars as compared to conventional rail equipment promises to be the salvation of many branch lines, many of which have had to discontinue service or will soon be compelled to do so because the expense of operating steam equipment exceeds the revenues obtainable for the service. Many of the smaller railroads have been using motor equipment for some time with such success that the larger railroads are now planning to use it on branch lines.

#### New Cars Larger

Several Mack rail cars using for the most part components employed in the Mack AB model truck have been in use by some short line roads for some months, but the cars ordered by the New Haven will be much larger and make a higher speed than those now in use. They will seat 36 as against 31 passengers, and will, in addition, have a baggage room 6 x 9 ft. at the rear. The engine and several other component parts are the same as are used in the Mack AC truck, but the leading four-wheel truck, rear axle and wheels, and the high speed reverse transmission which permits of operation in either direction at about the same speed, are special.

The major specifications of the new Model AC rail car are as follows: Four-cylinder engine, 5 x 6 in. with magneto ignition. Transmission, 4 speeds forward and 4 reverse. Final drive, shaft to bevel gear axle without differential, geared 4.53 or 5.36 to 1 and giving maximum speeds of 35 or 29 m.p.h. respectively. Wheels, forged steel, 20 in. front, cast steel 40 in. rear with locomotive steel tires shrunk on. Brakes on all six wheels, operated manually or by air. Springs, semi-elliptic front and rear with rubber shock insulators. Wheelbase, from center of leading truck to center or rear wheel 22 ft. Body, wood and steel, or all steel construction, inside dimensions 27 ft. 3½ in. by 9 ft. Electric starting and lighting and exhaust heating are provided for.

#### HAYNES BEFORE SENATE

WASHINGTON, Oct. 17—Elwood Haynes, president of the Haynes Automobile Co., appeared before the Senate

Committee on Manufactures to advocate the adoption of a metric system in this country. He explained the formula of the plan in detail in an effort to denote its simplicity and then compared it with the English system which was declared to be cumbersome and lacking in definiteness in terms used.

He was not speaking for adoption of the metric system particularly as an automobile manufacturer, but urged a change to this plan for general use and as the most efficient method.

### Durant May Establish Canadian Export Plant

MONTREAL, Oct. 18—Announcement is made by A. L. Caron of Caron Bros., after a conference in Toronto with W. C. Durant, president of Durant Motors of Canada, Ltd., that the new corporation is considering the establishment of a factory here which will give employment to approximately 2,000 men.

NEW YORK, Oct. 18—It was stated to-day at headquarters of Durant Motors, Inc., that consideration is being given the plan of establishing a factory in Montreal to manufacture cars for export. Nothing definite has been determined but a decision is expected within the next 30 days. If the plan is adopted it is probable the factory of Caron Bros. will be purchased. Caron may be associated with the Durant interests if his plant is taken over.

### Authorizes 100 Ford Tractors for Germany

DETROIT, Oct. 17—The Ford Motor Co. reports that foreign trade conditions are constantly improving. The Highland Park plant is making knock-down shipments to Buenos Aires and Copenhagen by way of New York. Sales in England are as good as they ever have been and the Ford business there is one of the sensations of the business world. Production at the Manchester plant is being maintained at 1000 a week.

The Inter-Allied Commission has authorized the shipment of 100 tractors to Germany. The machines will be made at the Ford plant in Cork, Ireland.

### Orders Portage Plant Sold to Seiberling

AKRON, Oct. 17—The Portage Rubber Co. has been ordered sold to F. A. Seiberling, formerly president of Goodyear Tire & Rubber Co., unless a new petition of demurrer is filed in 10 days by Harry L. Snyder, referee in bankruptcy. Creditors will receive between 75 cents and 80 cents on the dollar.

Liquidated claims amount to \$1,800,000; cash and accounts receivable, less reserve for doubtful accounts, amount to \$600,000. Inventory, which was figured at \$840,000, has appreciated to approximately \$1,000,000 since the receivership was inaugurated.

## Outlines Position of Stewart-Warner

### President Smith Says System Will Be Little Affected If In- junction Stands

CHICAGO, Oct. 17—C. B. Smith, president of the Stewart-Warner Speedometer Corp. of this city, in a formal statement points out the company's position with reference to the unfavorable decision of Judge Carpenter in the United States District Court in the litigation relating to patents on its vacuum feed tanks and explains that the company's manufacturing operations cannot be disturbed by the final outcome of the suit. President Smith says:

"In the recent decision by Judge Carpenter in the United States District Court in the case of Seager & Harrington vs. Stewart-Warner Speedometer Corp., concerning the vacuum tank manufactured by the Stewart-Warner corporation, it seems to be understood by the public that the Stewart-Warner corporation will no longer be in a position to manufacture what is known as the 'Stewart-Warner Vacuum System.'"

"The following are the real facts as issued by our patent attorneys:

"First—The decision does not open the way for the owners of the said patent to enter into the manufacture of vacuum feed devices which it enjoins us from making.

"Second—The recent decision of the United States Circuit Court of Appeals in the Sixth Circuit, in the case of Stewart-Warner Speedometer Corp. vs. Sparks-Withington Co., strongly sustaining the patent claims under which the Stewart vacuum system is made, has effectually prevented and will prevent either the Seager-Harrington patent owners or their licensees from entering upon the manufacture of the Stewart vacuum system.

"Third—Even in the highly improbable event that the United States Court of Appeals of the Seventh Circuit should confirm the decision of the District Court on the Seager-Harrington patents, so that the injunction (now pending appeal) should come into effect, preventing the continuation of the present installation, the Stewart vacuum system would have to be changed only in a minor feature not at all vital to its efficiency in order to be entirely clear of the Seager-Harrington patents as most broadly construed by the recent decision of the District Court.

"Fourth—Car builders who have been dependent on the Stewart vacuum system for their equipment have therefore no occasion to be disturbed by this decision, as the Stewart-Warner Speedometer Corp. will be in a position to continue manufacture of vacuum feed devices of the same dependability as the present device and installation."

#### J. KARL BAIN DIES

INDIANAPOLIS, Oct. 17—J. Karl Bain, president of the Motor Appliance Co. of Detroit, was found dead in his room in a Fort Wayne hotel last night. He left Indianapolis Saturday afternoon for Detroit. He was secretary to Charles M. Fairbanks while the latter was vice-president from 1897 to 1905.

## Steam Cars Making New Popularity Bid

Two Will Appear in Market Near  
Show Time—Others in  
1922

DETROIT, Oct. 17—Steam cars are to make a new bid for popularity in the near future. At least two will make their appearance some time close to the regular show season and two others are expected on the market some time in the early spring or summer of 1922.

The most advanced of the new crop of steamers is the Coats, several announcements on which have already been made and for which its producers, Coats Steamers, Inc., of Indianapolis, hope to establish a strong demand early in 1922.

Scott Newcomb Motor Car Co. of St. Louis has a new steam car which its engineers proclaim to be correct in design from mechanical and economic viewpoints. Its steam producing principle is said to have overcome the faults commonly experienced in steamers and to present a thoroughly workable application.

Like the Coats, the Scott-Newcomb car has passed beyond the experimental stage and is rapidly nearing the market.

Other steamers known to be in the experimental stages are one to be produced by the Barlow Steam Engine Syndicate, this city, and another the conception of O. C. Trask of Trask-Kennedy Co., this city, automobile dealers. Of the latter too little is known except that they will be steam cars along new lines.

## Chassis Components Are Olympia Feature

LONDON, Oct. 15 (*By Cable*)—The truck show at Olympia opened yesterday with a big display of gasoline vehicles as well as a fair showing of steam and electric trucks. A feature of the show was the number of chassis components.

There was a large display of municipal trucks and covered coaches which promise to supplant the open type. Few novelties were to be found.

The general tendency of prices is downward.

While the attendance was not large, the opening speeches indicated a fairly optimistic outlook. The textile trade is improving and a sharp cut in the price of steel has just been announced.

There was a fair representation by American makers, most of whom displayed small vans. The show included 80 vehicles besides 122 displays of component parts and tires.

## AUDITING PAN-AMERICAN

DECATUR, ILL., Oct. 18—Auditors now working upon the books of the Pan-American Motors Corp., producers of motor cars and motor trucks, believe that there is a shortage of \$20,000 to

## BUS MORE ECONOMICAL THAN RAIL, TEST PROVES

NEW YORK, Oct. 19—A test conducted by the Society of Automotive Engineers to determine the relative cost of railroad and motor bus transportation over long distances proved the motor vehicle to be distinctly more economical. The test was a trip from New York to Aberdeen, Md., and return, a distance of 352 miles. The total running time for the motor bus was 18 hours, making an average speed of 19 miles an hour.

The entire cost of the trip for gasoline, oil, wear on tires, depreciation on the bus, driver's wages and expenses, with 22 of the 25 seats occupied, was less than 1.25 cents per passenger mile. The railroad coach fare is 3.6 cents a mile. The passengers on the trip were members of the Society of Automotive Engineers.

\$40,000, nearer the latter figure, according to a statement from President Edward Danner. The auditors were placed upon the books when the disappearance of W. A. Phares, secretary-treasurer, became known.

## New Level of Prices Established by Essex

DETROIT, Oct. 20—The Essex Motor Car Co. has announced further price reductions as follows:

	Old Price	New Price
2-passenger .....	\$1,375	\$1,195
5-passenger .....	1,375	1,195
Coupe .....	1,880	1,395
Sedan .....	2,230	1,995

The reductions, it is stated, are made on anticipated market conditions in 1922. Open models are now \$180 lower than ever before. The reduction on enclosed models represents \$600 since September, 1920.

## DIXIE FLYER LOWER

LOUISVILLE, KY., Oct. 17—The Kentucky Wagon Mfg. Co., manufacturer of the Dixie Flyer, has made the following price reductions:

	Old Price	New Price
5-Touring .....	\$1,445	\$1,345
Sport touring .....	1,945	1,545
Roadster .....	1,445	1,345
Coupe .....	2,295	1,995
Sedan .....	2,345	1,995

These prices are f.o.b. factory and are subject to the war tax.

## OGREN INCREASES PRICES

MILWAUKEE, Oct. 17—The Ogren Motor Car Co. has made the following upward revision in its prices:

	Old Price	New Price
4-passenger .....	\$3,850	\$4,350
5-passenger .....	3,750	4,250
7-passenger .....	3,900	4,375
Coupe .....	5,000	5,200
Sedan .....	5,400	5,500

The company has changed to a Continental 6-T De Luxe engine.

## Dealers Opposing Tire Adjustments

National Association Will Also  
Take Up Question of Faulty  
Construction

CLEVELAND, Oct. 17—Delegates to the first convention of the National Tire Dealers Association, which convenes here tomorrow, will take action on a resolution which will be offered to put the association on record in favor of the elimination of all adjustments on tires. Representative dealers, who are backing the resolution, take the position that the adjustment is something that flares back on both the dealer and the manufacturer. The consumer passes it on to the dealer and the latter to the manufacturer.

The convention will be asked to go on record in favor of the manufacturer's replacing without charge, a tire that breaks down through faulty construction. If it is the consumer's fault he should be forced to buy a new tire, according to the terms of the resolution.

Another resolution will provide that the association shall propose and back legislation that will compel all dealers to tell patrons whether they are purchasing first or used tires.

F. A. Seiberling, former president of the Goodyear company at Akron, who is now building up a chain of tire companies, is on the program for an address on "The Future of the Rubber Industry." C. L. Nevin, assistant governor of the Federal Reserve Bank, will deliver a talk on the business outlook and E. S. Babcox, vice-president of the India Rubber Co., on "A Review on the Value of Co-operative Organization," at a banquet held at the close of the convention. A trip to Akron and Kent for a view of some of the largest plants in the industry and an exhibit of tires and accessories will be among the features of the meeting.

## No 3300 Truck Order for China, Hoover Says

NEW YORK, Oct. 17—Current reports that the Chinese Government was in the market for 3300 trucks and had closed a deal with a Canadian firm were denied by the Automotive Division of the Department of Commerce in a communication to the National Automobile Chamber of Commerce.

Merchants and officials in Shanghai were specially interviewed on this subject by the United States Commercial Attaché at the cabled request of this newly created division. They were of the opinion that the number of trucks reported sold to Shanghai Motor Co. was entirely out of proportion to the present market demand and furthermore that the Chinese Government has no funds available for subsidies to encourage motor truck transportation.

## Considering Future of Scripps-Booth

May Be Sold as Going Concern—  
Liquidation of Affairs  
Possible

DETROIT, Oct. 20—Officials of the General Motors Corp. are meeting here to-day to formulate definite plans for the future of the Scripps-Booth Corp. There is a strong probability that it may be sold as a going concern, but it is possible that its affairs may be liquidated.

Present plans call for an announcement that manufacture of the cars will be discontinued. This probably will be followed by a reduction in prices on those still on the market to insure immediate sale.

It has been proposed to move the present factory equipment from Detroit to another of the General Motors plants, whose organization would take over the servicing of Scripps-Booth cars now in the hands of owners and those which will be sold.

### Sarver to Be Transferred

Tentative plans call for utilization of the Scripps-Booth plant as a factory for the manufacture of Buick bodies. It is expected that A. H. Sarver, president and general manager of Scripps-Booth, will be transferred to another place in the General Motors organization. An effort will be made to supply Scripps-Booth distributors and dealers with some other General Motors line if they care to take it on.

The Scripps-Booth Co. was organized in 1916 to manufacture a light moderate price car. It was successful for some time, but its business eventually fell off and it was taken into the General Motors organization by W. C. Durant.

The General Motors Corp. owns 55,204 shares of the 60,275 shares of Scripps-Booth stock outstanding. The public holds 5071 shares.

### Corporation Formed in 1916

The Scripps-Booth Corp. was incorporated July 28, 1916, in New York, and acquired all the outstanding capital stock of the Scripps-Booth Co., manufacturer of Scripps-Booth cars, and the Sterling Motor Co., manufacturer of motors. The plants of both were in Detroit. The corporation issued in exchange for the stock of the companies it took over, 32,290 shares of its own capital stock which had no par value.

The corporation offered 25,000 shares for public subscription at \$50 a share in July, 1916, and 62,710 shares were offered to stockholders for subscription at \$8 per share on or before Nov. 1, 1917, to the extent of 1 1/10 times their holdings. At the time it was absorbed by General Motors no dividends had been paid.

When it was taken over by General Motors, A. H. Sarver was president of the corporation and W. H. Little was vice-president. Both retained their positions under General Motors management, but

## N. A. C. C. ACTS TO CURB HOTEL RATES AT SHOWS

NEW YORK, Oct. 20—The National Automobile Chamber of Commerce already has taken steps to prevent profiteering by New York and Chicago hotels during the automobile shows. A questionnaire has been sent to all hotel managers asking for their regular rates and other information.

They are asked to go on record as to whether they would require that a room be taken for a week regardless of the number of days it is used during the show and whether there will be any increases in rates because of the probable demand for accommodations.

Little has been in poor health for a long time. Directors of the corporation when it was purchased by General Motors included three men who later became prominent in the General Motors organization. They were W. C. Sills, F. W. Warner and Edward Ver Linden. Warner and Ver Linden have joined forces with W. C. Durant.

## Dodge Makes Ready for Canadian Plant

DETROIT, Oct. 17—Arrangements have been practically completed by Dodge Brothers for the manufacture of cars in Canada. A Canadian company with the same owners and officers as the American company has been formed and negotiations for a factory site in Ojibway, one of the border cities, are near the closing point.

An executive at the Dodge factory said they were prepared to go in for manufacture in Canada on a large scale as soon as they consider conditions right. This is not likely, however, to be for some time to come.

The Ojibway site, of 24 acres, on which the options are held adjoins the plant of the Canadian Steel Corp., Ltd. Funds have been placed in Canadian depositories coincident with the forming of the company, so that all preliminaries have been complied with pending the decision to proceed with construction.

Up to this time the Dodge business in Canada has been handled through a dock leased from the Canadian-Pacific Railroad, on which Dodge cars built in the United States were stripped of tires, windshield, lamps and batteries, and Canadian products substituted. The cars were run over to Canada under their own power.

### SAVAGE BUYS CANADIAN SITE

DETROIT, Oct. 17—The Savage Automotive Co., incorporated in Toronto as the Canadian branch of the English company, has purchased a site at Sandwich, Ont., for a factory and it is expected it will build a light car along the lines of the British product.

## BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.

The local money market last week displayed a firmer tone than in the previous week. Call money ranged from 5 per cent to 6 per cent during the week, with most of the business done at the latter figure. The range for the previous week was 4½ per cent to 5½ per cent. The stiffening of rates was attributed in part to Government withdrawals on Saturday from local banks of \$117,000,000 in preparation for maturing certificates of indebtedness and interest payments.

On Monday of the present week, following Government disbursements in excess of the withdrawals, call money renewed at 5 per cent with a low of 4 per cent, while on the "outside" market funds were available at 3½ per cent. Time money showed a firmer tone toward the end of last week when rates advanced to 5½ per cent for 60 and 90 days' paper, as against 5¼ per cent to 5½ per cent in the previous week. The longer maturities up to six months were unchanged at 5½ to 5¾ per cent. The commercial paper market remained unchanged, with few transactions.

The statement of the Federal Reserve System as of Oct. 11 showed a decline in the reserve ratio from 69 per cent to 68.5 per cent. This was a consequence of decreased gold reserves of \$3,667,000, increased bills on hand of \$23,608,000 and \$28,533,000 in deposits. Federal Reserve note circulation declined \$6,002,000. The statement of the New York Federal Reserve Bank, showing a decline of \$22,098,000 in total gold reserves, reflects the movement of funds to the interior to satisfy seasonable crop demands.

Gold imports for the month totaled \$66,515,000, as against \$39,110,000 in the corresponding month of 1920, while exports were \$2,448,000 as against \$17,129,000 in September of last year. As a result, the net excess of imports amounted to \$64,067,000 as compared with \$85,540,000 in August. The excess of gold imports for the nine months' period amounted to \$54,422,000, as against an excess of gold exports for the corresponding period of 1920 of \$60,443,000.

There have been further evidences of improvement in the industrial situation, especially as regards steel, copper and oil, although the horizon is at present clouded by the possibility of a general railroad strike by the members of the Four Brotherhoods on Oct. 30.

### CORRECTION

CLEVELAND, Oct. 18—The statement was made by AUTOMOTIVE INDUSTRIES of Oct. 13 in its announcement of the National Association of Automotive Bankers that the headquarters would be located in the Gotham National Bank building "in this city." The headquarters will not be located in Cleveland but in the Gotham National Bank building, New York.

## Willys to Establish Indianapolis Branch

**Distributors Whose Services Are  
Discontinued Will Remain  
as Dealers**

INDIANAPOLIS, Oct. 17—The Gibson Co. within the near future will discontinue its retail and wholesale distribution of Overland and Willys-Knight motor cars, which will be assumed by a new Indianapolis Willys-Overland branch, and will henceforth devote its entire organization and energy to its automotive accessory and equipment business.

The Gibson company is one of the oldest automobile and accessory concerns in the country. It began the distribution of Overland automobiles and of automotive equipment in the early days of the industry, 23 years ago. Its Overland territory has been the largest of any distributor.

In taking over the motor car distributing departments the Willys-Overland Co. will pay cash to the Gibson company for its automobile and parts departments, and will conduct the Indianapolis branch in the same building where the business has been located. The Gibson company will retain part of its present headquarters. R. E. Butler will be the branch manager.

### Distributors to Be Dealers

TOLEDO, Oct. 18—Many of the Overland distributors who have been eliminated from the Willys-Overland organization under the plan which will become effective Nov. 1, will remain as individual dealers. Dealers who formerly sold cars under distributors will deal direct with the factory distributing organization, which is Willys-Overland, Inc.

A considerable increase in export demand for Overland cars has been noted in the past few days. More than 1,000 orders for foreign shipments were received last week.

After payment by the company of another 10 per cent on its bank loans on Nov. 1, reducing them to \$16,000,000 from the peak of \$43,000,000 only a few months ago, the company will still have about \$6,000,000 in cash.

### Harper Joins Brother

PHILADELPHIA, Oct. 17—John N. Willys, head of the Willys-Overland Co., and Walter P. Chrysler, executive vice president and general manager, made addresses at a get-together meeting of 600 dealers in Overland and Willys-Knight cars, at which Harry B. Harper, retiring head of the Overland-Harper Co., was toastmaster.

Following the speeches, the dealers, who were from Eastern Pennsylvania, Southern New Jersey, Delaware, Maryland, Eastern West Virginia and portions of North Carolina, were introduced to the new house organization of Willys-

Overland, Inc., which succeeds the Overland-Harper Co.

Harper is now associated with his brother, Paul I. Harper, in the firm of Harper & Harper, handling Handley-Knight and Willys-Knight cars. Paul I. Harper for eight years served under Henry Ford. In 1910 he organized, with another brother, the Harper-Overland Co., in Washington. At the outbreak of the war he sold out his interest and went to France. After being mustered out of service in 1919, he joined the Overland-Harper Co., of Philadelphia, as secretary and treasurer.

### Drops Springfield Branch

SPRINGFIELD, MASS., Oct. 17—The Willys-Overland Co. is to discontinue its Springfield branch Nov. 1, and the distribution of its cars in this territory will be placed in the hands of some reliable dealer. This is in conformance with the company's policy of reducing costs and getting in closer relations with the dealers.

The Willys-Overland Building will be sold. This building was erected five years ago, and is one of the best-appointed sales and service establishments in New England. It is understood that William G. Northrup, the present manager of the Springfield branch, is to take charge of the Boston branch, which will be the distributing medium for this district.

### No Change in Republic

ALMA, MICH., Oct. 18—Colonel Frank E. Smith, first vice-president and general manager of the Republic Sales Corp., denies the rumor that the establishment of factory branches in Boston, New York, Baltimore, Pittsburgh, Detroit and Chicago foreshadows the replacing of the company's present system of distribution.

## Government Prepares Mobilization Survey

(Continued from page 787)

tation. Figures compiled by this agency indicate that all records for highway construction have been shattered this season and as a consequence thousands of miles of roads are open as safe and dependable arteries of commerce.

Post Office officials are speeding up repair work in garages and getting airplanes ready for service. The department has about 250 serviceable aircraft and this figure is greatly augmented by War and Government flying machines. It is believed that reserve aviators will be called into service if it is necessary to operate these planes for transportation of mails.

This department for a time operated a motor truck service to Washington, furnishing transportation for farm products. This system of truck to market may be revived. Government officials have stated that motor vehicles will be operated if necessary under Government supervision and with armed guards to prevent interference.

## Strike Will Find Plants Prepared

**Factories Are Well Stocked for  
November Business—Have  
Coal Supplies**

DETROIT, Oct. 18—Leaders in the automotive industry, though agreeing that the railroad strike would be a catastrophe to the business life of the country, are of the opinion that so far as the industry is concerned, it could not come at a more opportune time.

So far as shipping of finished cars is concerned, roads all over the country are open in November and driveways would not be impeded in any way by snow or weather conditions. No one wants to go back to driveways, but no transportation tie-up will stop deliveries except to far distant points.

### Driveways Unhampered

Unimpeded roads will also permit factories to use their trucks to bring in supplies where needed, although most factories find themselves fairly well stocked for taking care of November business. Factories with their own power plants are well stocked with coal in most instances, and the Detroit Edison Co., with its lesson of the last tie-up still fresh, has ample stocks for the winter months.

The cost of bringing in material by truck, where it will have to be resorted to—and the industry is resolved that no rail tie-up shall interfere with its sales—will mean an extra burden in costs, but all costs will be absorbed to keep trade channels open.

If the strike is long lived it is thought that another strong argument will be provided for utilizing motor trucks for all short haul work and that many industrial houses will become permanent users of truck transportation in intercity deliveries.

## C. A. Benjamin Becomes Marmon Representative

INDIANAPOLIS, Oct. 18—C. Arthur Benjamin, one of the most widely known men in the automobile field, has become associated with Nordyke & Marmon Co. as a district representative. Benjamin's activities will center in the East, his territory including New York, Philadelphia, Boston, New Haven, Poughkeepsie, Providence, Springfield, Portland, and other cities in that vicinity.

When Benjamin left the bicycle business some years ago he became associated with the Franklin Motor Car Co. He was sales manager from the time the first car was sold until 1906. Since that time he has been in the automobile division of the American Locomotive Co. until that division was discontinued, and as C. Arthur Benjamin, Inc., held the Packard agency in Syracuse. He was in the service of the Government during the war.

## MEN OF THE INDUSTRY

**William Beckman**, for many years assistant to Fred S. Duesenberg and prior to that chief engineer of the Loew-Victor Engine Co. of Chicago, is now vice president in charge of engineering of the newly formed Richelieu Motor Car Corp. of Asbury Park. The company is assembling chassis in a temporary plant while the bodies are being fitted at the plant of the Fleetwood Metal Body Co. The directors of the Richelieu corporation are interlocking with those of the Rochester Motors Corp. and the car will be powered with a four cylinder Rochester-Duesenberg engine.

**H. R. Sturgeon** has become associated with the John O. Munn Co. Sturgeon was formerly connected with the advertising activities of the Willys-Overland company, first at the Toledo headquarters and later as advertising manager of the John N. Willys Export Corp. at New York. Before that he was assistant advertising manager of the F. B. Stearns Co. at Cleveland. C. E. Duncan, formerly connected with the Willys-Overland company and the White Co., has been elected a director in the Munn concern.

**William S. Knudsen**, associated with the Ford Motor Co. for the last ten years, has resigned from that organization to become general manager of the Ireland & Matthews Mfg. Co. Before joining the Ford company Knudsen served as general superintendent of the John R. Keim Mills, Inc., Buffalo.

**Henry Thomas Platz** has resigned as chief engineer of the Alvo Co., automobile headlight division, at Ashland, Ohio, to become engineer of design for the Gray & Davis Lamp Corp. at Amesbury, Mass. He formerly was chief engineer of the C. M. Hall Lamp Co., Detroit.

**H. H. Doehler** of the Doehler Die Castings Co., Brooklyn, is one of the speakers booked for the factory management class of the University of the City of Toledo this winter. Many officials of the Willys-Overland and allied automotive plants in Toledo are enrolled in the class.

**William A. Bechberger** has severed his connection with the New York office of the Fisk Rubber Co., where he had charge of fabric purchasing. He was for ten years the company's purchasing agent at the plant in Chicopee Falls, Mass., before removing to New York.

**White Co.**, Cleveland, has established a factory branch in Louisville for the selling and servicing of White motor trucks. Charles M. Moon has been appointed branch manager. The branch has taken over the business of the White Truck Co. of Louisville.

**Homer McKee**, formerly in charge of Cole Motor Car Co. sales and advertising, has been appointed advertising counsel to the Cole organization. **Charles S. Crawford**, formerly chief engineer of the Cole company, has been named engineering consultant.

**W. A. Sullivan**, formerly sales representative for Oldsmobile in Pennsylvania territory and before that advertising manager of Oakland Motor Car Co., Pontiac, has joined the staff of the Automobile Trade Directory in Detroit and Michigan territory.

**George L. Sawyer**, formerly sales manager of material handling machinery for Barber-Greene Co. of Aurora, Ill., has been appointed New York representative of the Universal Crane Co. of Elyria, Ohio. His headquarters will be in New York City.

**Frank H. Gibbes**, who has been vice-president of the Gibbes Machinery Co., distributor

of Packard, Paige and Durant cars in South Carolina, has been elected president to succeed his brother, A. M. Gibbes, who died a few weeks ago.

**W. T. McHatton**, formerly of the Republic Motor Truck Co., has been appointed southwestern district representative of Ruggles Motor Truck Co., with headquarters at Denver.

**E. E. Wentz**, for five years in the Maxwell-Chalmers advertising department, has resigned to go into business under the name of Cady & Wentz with offices in Detroit.

**E. C. Hugh** of The Hugh Co., Buffalo, has returned from a short visit to Europe, taken for the purpose of disposing of surplus stocks of American-made millimeter size tires.

**E. T. Herbig**, sales manager of Service Motor Truck Co., Wabash, Ind., has resigned to become associated with General Motors in the sales organization.

**Frank G. Vanderhoff** has been appointed sales manager of the Ray Battery Co. of Ypsilanti, succeeding Wallace B. Blood, who has resigned.

**J. T. Aubrey**, advertising manager of the Packard Motor Car Co., has resigned to become advertising manager of Hearst's International.

**Henry Farrington** has been appointed sales manager of the Antigo (Wis.) Tractor Corp., which is now in production and making deliveries.

**Milton R. Standish** has been appointed vice-president, in charge of promotion of the Gill Storage Battery Co., San Bernardino, Cal.

**Dever Waters** has been appointed sales manager of the Schwarz Wheel Co., Philadelphia.

Use of Parenti Plans  
Restrained by Court

**BUFFALO, Oct. 17**—Three former members of the Parenti Motor Corp. are restrained in an injunction, issued by Justice Pooley in the Supreme Court, from using or imparting to anyone plans, ideas and features, said to have been developed by the president of the corporation, Joseph S. Parenti.

Those included in the restraining order are Louis F. Vremsak, Willard C. Wheeler and John W. Lease.

Parenti alleges unlawful use has been made of certain drawings and plans, covering exclusive and patented features of the automobile, bearing his name, by the Adria Motor Car Corp. of Batavia, N. Y., of which Vremsak, Wheeler and Lease are officials. He charges that these men obtained secret possession of blue prints and patents in the Parenti plant in this city, while they were assisting him in experimental work. They are now using these, he alleges, in advertising that they intend to build a car, which will include all the alleged exclusive features of the Parenti car.

## FORM ADANAC MOTORS

**MONTREAL, Oct. 18**—The Adanac Motor Corp., Ltd., Lachine, Que., has been organized with a capital of \$50,000 to manufacture a chassis converter for use in connection with a standard Ford chassis. The capacity of the vehicle will be two tons. The final drive is of worm type.

## FINANCIAL NOTES

**Stromberg Carburetor Co. of America, Inc.**, for the six months ended June 30, 1921, reports surplus after charges and Federal taxes as \$51,544, equivalent to 68 cents a share earned on the 75,000 shares of capital stock of no par value. Earnings for this period were \$278,237; other income, \$10,005; administration and general expenses, \$221,698; Federal taxes 1921, \$15,000; surplus, \$51,544; previous surplus adjusted, \$2,352,669; total surplus, \$2,404,213. The consolidated balance sheet as of the above date shows the assets to be \$3,242,823, with cash placed at \$188,978; notes and accounts payable, \$304,609, and inventories, \$699,330. The liabilities include notes payable, \$100,000; accounts payable and accrued accounts, \$51,840; reserve for depreciation, \$363,133; reserve for Federal taxes, \$48,637.

**Fisk Rubber Co.** has filed a mortgage for \$10,000,000 to the Chase National Bank of New York at the registry of deeds in Springfield, Mass. This is in accord with action recently taken by the stockholders in connection with the absorption of the Federal Rubber Co. and the Nineget Co. The mortgage is to secure an issue of 20-year, 8 per cent sinking fund gold bonds in denominations of \$500 and \$1,000, payable in 1941.

**Hendee Mfg. Co.'s** annual report for the year ended Aug. 31, 1921, shows a net loss after charges and reserve for adjustment of inventories, etc., of \$912,078, as compared with net profits of \$759,914 in the preceding year. The sales for the year were \$4,139,445, as against \$9,055,357 in 1920, and the costs and expenses in 1921 were \$3,979,057, compared with \$8,301,238 last year.

**Elgin Motor Car Corp.** through the Argo, Ill., State Bank is offering \$500,000 8 per cent notes at par, dated June 1, 1921; due each June 15, \$100,000 1922, \$150,000 1923 and \$250,000 1924; convertible into common stock at par at any time before maturity. The purpose of the issue is to retire bank loans and enlarge working capital.

**Kelly-Springfield Tire Co.'s** 10-year 8 per cent sinking fund gold notes are now ready for delivery in engraved form, with coupons attached, in exchange for and upon surrender of the temporary notes at the office of the Central Union Trust Co., New York City.

**Kess-Line Motor** has obtained the approval of the Michigan Securities Commission for the issuance of \$500,000 in preferred stock, and 25,000 shares of non-par common stock has been validated.

**Victor Rubber Co.** will pay on Oct. 25 to holders of record Oct. 15 the 1½ per cent preferred dividend which should have been paid in August of this year.

**H. H. Franklin Mfg. Co.** has declared the regular quarterly dividend of 1½ per cent on the preferred stock, payable Nov. 1 to stock of record Oct. 20.

**Winther Motor Truck Co.**, Kenosha, Wis., has increased its capital stock from \$22,000,000 to \$61,000,000.

## ORDERS TRUCK DIVIDEND

**DETROIT, Oct. 17**—Creditors of the Famous Motor Truck Co., St. Joseph, Mich., will receive a 15 per cent dividend under the terms of an order entered at the final hearing before the bankruptcy referee. Claims totaling \$92,000 were presented, the largest for \$15,650 being from Frank L. Wilkinson, president of the company.

## INDUSTRIAL NOTES

**Biever Casting Co.**, Slinger (formerly Schlesingerville), Wis., has taken over and will place into operation at once the Slinger gray iron foundry. The Biever company has been incorporated with \$25,000 capital by John H. and Edmund J. Biever. The plant has been idle for nearly a year. John Biever was for many years connected with the Gilson Mfg. Co., founder and machinist, Port Washington, Wis., and Edmund Biever with the Montana Tractor Co. of Oconto, Wis. They will specialize in light and medium weight gray iron castings for the automotive and agricultural implement industries.

**American Motor Parts Co.** of Indianapolis, manufacturer of gas engine, automobile and tractor parts and operating a branch at East Moline, Ill., has been incorporated in Illinois with capital stock of \$200,000, of which \$52,820 is to be employed to do business in that state. The president is William Goldstein and the secretary Harry Goldstein, both of Philadelphia. The East Moline branch has moved from the R & V Engineering Co. plants to the Ideal Milling Co. building. James L. Westphall is general manager of the East Moline annex.

**Auto-Motor Corp.** of Charleston, W. Va., which manufactures automobile and mining car motors at Dunbar, near that city, will transfer its general offices and plant to Point Pleasant, W. Va., within four months. L. C. Pritchard, vice-president and general manager, states that ground will be broken within three weeks for the first unit. The total cost of the plant will be \$250,000. It is expected actual operation will be started by February. In the meantime the plant at Dunbar will continue operations.

**Northwest Engineering Works**, Green Bay, Wis., manufacturing cranes and hoists and specializing in a yard crane mounted on a crawler type tractor chassis similar to war-time tanks, has been reorganized as the Northwest Engineering Corp., with \$400,000 preferred stock and 1000 shares of non-par valued common stock. The officers are: President, F. W. Hurlbut; vice-president, W. T. Schmitt; secretary and treasurer, W. W. Mutter; general manager, H. G. Barkhausen.

**Andrew Nelson and Christian Hansen** have established a new plant at Racine, Wis., for the manufacture of passenger car and motor truck bodies, cabs, etc. Nelson formerly was superintendent of the body department of the Mitchell Motors Co. and Hansen for years conducted a trimming and painting shop in Racine.

**Kelly-Springfield Tire Co.** is about fifteen days behind in orders, notwithstanding that it is turning out 4300 tires a day, of which 2000 are being made at the Cumberland plant. Sales for September were \$2,423,000, as compared with \$1,862,000 for the same month last year.

**Moline Plow Co.** tractor plant at Rock Island, Ill., will start making motor engines for the Stephens automobiles Dec. 1. Equipment and machinery of various kinds have been purchased from the Root & Vandervoort Motors Co. and the work of transferring and installing the new plant is now under way.

**Midwestern Tractor Wheel Co.** of Detroit, manufacturing a patented tractor wheel with adjustable cleats, has purchased a site at Amherstburg, Ont., where it will erect a factory. Modern equipment will be installed at a cost of \$250,000. The company is capitalized at \$1,000,000.

**New Britain Machine Co.** will temporarily suspend the manufacture of the N. B. trac-

tors because of the buyers' strike. The closing down of the plant will affect about 50 men. A small force will be retained to assemble those tractors which have already been ordered.

**Harrison Radiator Corp.**, Lockport, N. Y., has bought property in that city at a cost of \$30,000 for an addition to its plant. The corporation is owned by General Motors and at present is operating at about 50 per cent. When normal the present plant employs 1200 men.

**Stanley Welded Wheel Co.**, North Tonawanda, N. Y., which is erecting a plant in that city, is expecting to be operating at an early date. The company will manufacture wheels for automobiles and will employ about 200 men at the beginning of operations.

**Parish & Bingham**, Cleveland, report that October sales and production are running ahead of September and anticipate that November and December output will maintain a good average.

**Adams Axle Co.** of Findlay has closed a contract with Durant Motors, Inc., to manufacture all axles and brake bands for the new Durant cars. The plant has 180 men at work now and expects to double this force soon.

**King Trailer Co.**'s entire assets at Ann Arbor, Mich., brought \$40,550 at public auction. W. L. Walz of that city was the purchaser.

**Lakewood Engineering Co.** of Cleveland has moved its Philadelphia office from the Widener Building to the Franklin Trust Building.

## Pierce-Arrow Nears Normal Conditions

**BUFFALO, Oct. 17**—Colonel Charles Clifton, chairman of the board of directors of the Pierce-Arrow Motor Car Co., has issued a statement in which he says that production and sales activities, which have been increasing gradually for the last three months, now have reached proportions rapidly approaching normal. The factory, he states, is running full time with a force of 4230 workers. He expects this force to be maintained, if not increased, during the next six months.

"Insofar as the automobile industry reflects general conditions throughout the country, our situation indicates a decided improvement in business," said Clifton. "Analyzing the business of the entire automobile industry we find we are getting more than our proportionate share. The unfilled orders we have on hand will keep the plant operating at its regular output until Dec. 1.

"The truck business shows a similar stimulation. In September we shipped twice as many trucks as for any other one month of the year. On Oct. 1 we had more orders on hand than on the first of any month this year."

## PICARD QUILTS AS JOBBER

**NEW YORK, Oct. 17**—A. J. Picard & Co., general automotive equipment jobber with headquarters here, has discontinued its jobbing business and will devote its energies hereafter to distribution of a number of products, including Stromberg carburetors and Gabriel snubbers, which the company has been handling for some time in addition to its jobbing lines.

## METAL MARKETS

**T**HERE is no mistaking the overplaying of their hands by those producing interests who announced a second \$5 per ton advance in their sheet prices, effective Oct. 15. In spite of undoubtedly inspired reports that announcement of the impending advance brought out large orders at the old price, the majority opinion in the trade is that the bait failed to work this time. Even those "independents" who constantly bewail present market prices which, they claim, do not permit them to make both ends meet, question the wisdom of resorting to so sharp an advance as \$5 per ton as a lure for attracting orders at the old price. It is fairly possible, however, that there was another motive connected with announcement of this advance. It is conceded that over the remainder of the year little aside from routine business will be placed. These orders will come through at any price and the thought underlying announcement of the advance might have been that it may bring out some orders at the old price and, in addition, increase the revenue from the slight amount of routine business to be expected in the coming two months. Obviously the \$5 per ton advance in prices for hot-rolled strip steel announced by a Sharon interest is based on the theory that what business in that commodity will come through in the immediate future will be of a strictly routine character and will be placed whether \$5 a ton is tacked on to the price or not.

It is only natural that in the foreground of discussion in trade circles early this week was the effect which the threatened railroad strike would have on the steel market. Aside from the modest number of telegrams with which producers were inundated, all asking that shipments of steel needed to comply with production schedules over the next few weeks be rushed forward with as little delay as possible, there has been no effect market-wise. It is recognized that while a tie-up of the railroads would curtail steel shipments there would be a corresponding curtailment in the shipments of the products into which the steel centers.

**Pig Iron.**—The reduction in iron ore freight rates of 28 per cent which pig iron producers contend can have no effect on the market for their product, until their present ore stocks have been consumed, has led to the uncovering of the fact that it does not take "a little more than two tons of iron ore to make one ton of pig iron," as frequently stated in the last few days, but only 1½ ton of ore. This figure is on the authority of the American Iron and Steel Institute.

**Steel.**—Buying by automotive consumers is sporadic. Youngstown reports state that the largest low-priced passenger car builder has ordered suspension of deliveries against certain hot-rolled strip contracts. The same interest, however, recently placed a good-sized order for sheet material to be converted into running boards. Another passenger car interest placed fresh orders for strip steel. But, although Ford, Dodge, Chevrolet and Oakland figure as buyers in the market, specifications for automotive steels have tapered off. Full-finished body sheets are in light inquiry. On the whole, it may be said that automotive consumers are marking time.

**Aluminum.**—All sorts of bargains continue to be offered, but automotive demand remains in abeyance.

**Copper.**—The market presents a steady appearance, but if there is any fresh consuming interest it is not visible to the naked eye.

# Calendar

## SHOWS

Nov. 14-15—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association. Fourth Regiment Armory.

Nov. 27-Dec. 2—New York, Automobile Salon, Hotel Commodore.

January—Chicago, Automobile Salon, Hotel Drake.

Jan. 7-13—New York, National Automobile Show, Madison Square Garden, Central Palace. Auspices of N.A.C.C.

Jan. 28-Feb. 2—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.

Feb. 6 to 11—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.

Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

Nov. 4-12—Car Show. Nov. 28-Dec. 3—Motorcycle Show.

Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.

Nov. 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.

Nov. 12-27—Buenos Aires, Annual Motor Show, La Pabellon de las Sosas, Automovil Club Argentino.

Nov. 26-Dec. 3—Shanghai, China, Automobile Show.

March, 1922—Santiago, Chili, Annual Automobile Show.

May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibit in connection with the Brazilian Centenary Association Automobilsta Brasileira.

## CONVENTIONS

Oct. 28—New York, American Iron and Steel Institute.

Nov. 1-4—New York, Industrial Relations Association of America.

Nov. 3—Indianapolis, Meeting of Friction Drive Engineering Society.

Nov. 14-19—Chicago, Annual Meeting and Business Exhibit of Automotive Equipment Association.

Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.

Nov. 21-23—Atlanta, Third Annual Convention of American Farm Bureau Federation.

Dec. 6-8—Chicago, Second Annual Meeting of American Petroleum Institute.

Dec. 10—New York, American Institute of Mining and Metallurgical Engineers.

Dec. 20—Philadelphia, American Society of Mechanical Engineers.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

Jan. 17-20, 1922—Chicago, American Road Builders Association.

## S. A. E. MEETINGS

Detroit, Oct. 21, Nov. 18, Dec. 23, Feb. 24, March 24, April 28, May 26.

New York, Jan. 11-14, 1922—Annual Meeting.

Chicago, Feb. 1  
Minneapolis, Feb. 8—Tractor Meeting.

## To Pay All Standard Creditors Pro Rata

### Receiver Withdraws Request to Meet Claims of \$100 or Less in Full

CLEVELAND, Oct. 18—A million dollars in checks will be mailed on Nov. 1 from the general offices of the Standard Parts Co., in this city, to creditors of the company.

The distribution will be made under an order granted by Federal Judge D. C. Westenhaver upon the application of the receiver, Frank A. Scott.

The request of Scott for authority to pay in full the smaller creditors, whose claims are \$100 or under, was withdrawn and the disbursement will be pro-rated among them.

The condition of the Standard Parts Co., which has been in the hands of a receiver for more than a year, is generally accepted as evidence that business is on the upgrade here.

Another indication was given when creditors of the McGraw Tire & Rubber Co. were paid 10 per cent on their claims. Some time ago the creditors of the company agreed to extend the time for payment and the business has been such that the first dividend was paid on time. It is officially reported that the net profits of the company was \$85,000 in September, which is a substantial increase over July, but it is a decline from the peak earnings of \$109,000 in August. This company at present is making 2000 casings and 2000 tubes a day, and officials expect to continue that rate for the rest of the year.

There are still other evidences which point the same way. Business at the plant of the Jordan Motor Co. is running on a capacity basis, according to a statement of President Edward S. Jordan. He says the corporation is em-

ploying 30 per cent more men now than last month and that it is turning out about 400 cars a month. One day last week the company shipped 29 cars, but the average is around 24.

Under the leadership of certain industrial stocks, automobile among them, the stock market here showed considerable strength last week. White Motor moved up to 35, a substantial gain. Production at this plant has been increased 20 per cent.

## Paris Car Show Closes; 60,000 Attended Daily

PARIS, Oct. 15 (By Cable)—The Paris automobile show closed Sunday evening after being open 12 days. It was a complete success with the attendance averaging 60,000 daily. The amount of business done was satisfactory, particularly in the small and medium cars. Manufacturers believe that the depression is now over and that the coming year will be good. Sales were helped by the Government announcement this week of an immediate repeal of two cents a litre on gasoline tax. Further cut of one cent will be made Jan. 1. It is proposed to make the show annual.

## Plan Closes Market for Government Sales

WASHINGTON, Oct. 17—Co-ordination of motor transport facilities now owned by the various departments and bureaus of the Federal Government in this city will result in a saving of approximately \$20,000 per week. Col. Clarence O. Sherrill, Superintendent of Public Buildings and Grounds and co-ordinating officer for the District of Columbia under Director of the Budget Dawes, has devised a plan which he expects will prove efficient enough to keep the Government from the open market for some time.

## Conferees Report Road Legislation

### Few Changes Made in Highway Bill as It Was Passed by Senate

WASHINGTON, Oct. 18—Agreement has been reached in the conference of the Senate and House regarding the highway bill and the conference report will be submitted to Congress. The Senate provisions were in the main accepted by the House managers and the appropriation of \$75,000,000 for Federal aid was approved. The 60-40 plan of distribution of funds was likewise retained.

The changes made in conference were of a minor character. The conference increased the percentage for administrative purpose from 1½ to 2½ per cent. This percentage becomes available first and it is to be devoted to expenses incident to the administration of the act and to scientific research into highway problems. An effort was made to have the appropriations available immediately but the conferees decided to make it effective Jan. 1, 1922.

The passage of this bill will do much toward stimulating highway construction in 13 States where this activity has been held up indirectly, at least, for lack of funds and in seven States where Federal aid was essential to road development. The conference report apparently satisfies the agricultural bloc in the Senate and House. It was this coterie which assumed the responsibility for the defeat of the original Townsend bill.

## HATHAWAY HANDLING DURANT

KANSAS CITY, Oct. 17—The Hathaway Motor Co. has been appointed distributor for Kansas and western Missouri by Durant Motors of Michigan. The contract calls for 5,000 cars a year.

### Why the "Four"

#### Will Be the "Best Seller" in the Automobile Market Just Ahead

The car manufacturer who makes a fine "Four" to sell in the price range representing the big, broad market, can build into his car *all* of the essentials found in any automobile and at the same time he will have a wider margin to devote to those features which increase riding comfort, economy of operation and maintenance.

This car will be simple so that the average man who has to take care of his own car will encounter no excessive maintenance charges.

It will be lighter; it will deliver an average mileage of from twenty to twenty-four miles per gallon of gasoline; it will consume less lubricating oils and will give greater tire mileage.

Under such conditions, it is evident that the manufacturer with a limited engine allowance can build a fine four-cylinder car at a price that would skip more cylinders.

These conditions only increase the long established value of the Lycoming Motor to the car manufacturer.

The simplicity, strength and economy of the Lycoming Motor support the car manufacturer's product with his buyers and dealers by balancing good body value with good engine value.

*Write for test records and specifications.*

## FEDERAL BEARINGS

### UNIFORMITY

The Babbitt lining in every Federal Bearing shows the same tough, fine-grained, homogeneous structure because every Bearing is chilled immediately after it is lined.

### SOLIDITY

Every Federal Bearing is guaranteed absolutely free from porosity, because the process of manufacturing makes it impossible for the Babbitt to contain air while cooling.

### 100% BOND

Unlike all other methods of manufacturing Bearings, the Babbitt lining and Bronze Back of every Federal Bearing is Bonded UNDER PRESSURE while the adhering alloy is at a constant temperature.

### EXCELLENCE

Every Federal Bearing is manufactured from the highest grade materials, machined accurately and subjected to the most rigid inspection, because "FEDERAL, DETROIT" must be stamped on the back.

EVERY FEDERAL BEARING IS LINED BY  
**CENTRIFUGAL FORCE**

(Process protected by patents)

## Marketing Problems of the Automotive Industry

Decreased unit production costs have absorbed constantly increasing marketing costs for many years. A limit will be reached. Investigation, analysis and definition are needed in automotive marketing. The beginning of a series of discussions on this subject.

By Harry Tipper

**H**OW to get the goods from the factory to the user, with the least possible expenditure of time and money and in sufficient quantities to keep the factory running at full load, is rapidly becoming the great problem of industry.

Up to the war the manufacturing capacity of the United States was not quite large enough to equal the consumers' capacity to use the manufactured products. Except in raw materials, the United States was an importing country. Its excess of manufactured imports over exports was sufficiently large to intimate the absence of any surplus capacity to produce.

During the war the manufacturing capacity of the United States grew very rapidly, so rapidly that it increased something over 100 per cent. The present capacity is between two and two and one-half times the capacity of 1913.

There has been no such increase in the markets and, as a consequence, the competition in the near future will operate along different lines from the past.

In the automotive business the present capacity for production of vehicles is larger than the probable consumption for the next year or two. Prices have been reduced without much relation to the cost of

production. It is not likely that the cost of production will be reduced sufficiently to secure all the economies that are necessary. Meantime, the costs of distribution and marketing have increased very materially, including the physical costs of transportation, the cost of selling, advertising, the capital required for products in the course of distribution. They are not likely to decrease without changes in the methods, because the intensity of competition will make it necessary to spend more time and effort in securing the unit of sale.

Up to the present the expenditure for selling, advertising and distributing the product has not been analyzed very carefully. Experiments in merchandising, in advertising, and in the distribution of the product have been undertaken without much knowledge as to the probability of their success.

For a number of years production costs have been represented by a decreasing percentage of the sale price, while commercial costs have been represented by an increasing percentage of that price.

It has been possible in the automotive field for the manufacturer to add up his total costs and a percentage for his profit and to sell his product at the resulting price.

It is unlikely that this can be continued. It is more than probable that the manufacturer will have to determine the price at which he can sell his output and arrange to make his costs suit this price, or else eliminate a part of his profit. In other words, until the war, the seller in the United States usually governed the price; whereas, the situation in the immediate future means that the buyer will govern the price, and the seller's profit will depend upon his ability to arrange his costs within that price.

For a good many years it has been the custom to put the problem of cost reduction up to the production department. In the eyes of the manufacturer almost any expense has been justified in the selling or commercial end of the business. Little or no attempt has been made to analyze the expenditures of the commercial departments and the relation between these expenditures and their value to the organization. Very little has been done to analyze the field and channels of distribution, to determine the type of distributor and dealer necessary to the business and to determine cost of the various elements concerned in the handling and distribution of the products.

The cost of producing the automobile or truck has been less than 50 per cent of the price which the user was called upon to pay, and in the case of parts and accessories, it was frequently less than 30 per cent. All the rest of the cost arises out of the marketing or commercial necessities and inefficiencies.

Economic surveys show that the efficiency of production has been increased in the last twenty years, and the efficiency of distribution has been decreased, so that it takes more people to distribute a thousand dollars' worth of goods to the user than it did 20 years ago. A great deal of the sales and marketing effort has been based upon guesswork, impression and the fragmentary experience of individuals, without the checks established on the production side. Many of the costs of these marketing efforts have been overlooked, because the systems of cost accounting in commercial business have not been analytically arranged to indicate the relative costs of various sales and marketing operations.

Although it is obvious that the buying power of dealers varies greatly and that they are not all worth the same time and effort to secure their business, most manufacturers have conducted their marketing business as though all distributors and dealers were equally important. The sales, advertising and merchandising work has been conducted with almost equal attention to all types. Only comparatively few of the individuals in any community are either interested or capable of being interested in an individual product. Yet manufacturers have conducted their advertising work as though all individuals were equally important as possible buyers of the product and merited an equal amount of time and effort in the endeavor to induce them to buy.

Branches have been established with little relation to their necessity and value. Extra services have been added without any proper consideration of their influence.

The motions that are made in marketing and the department created for the purpose of assisting the sale, have been conducted with very little analysis of the relation between their value and their cost. Because these departments were concerned with getting orders and the orders were looked upon as the most important part of the business, expenditures were permitted that would have been immediately curtailed in any other branch of the establishment.

The marketing problem of the manufacturer to-day is the problem of investigation, analysis and definition. The commercial operations in his business, their relation to the sale of the product, their cost and their value in connection with the sale must be determined. Consideration must be given to the methods and channels of distribution, their relative importance, their grouping and the necessary values they exert in connection with his business.

The examination should include the habits of the user, his problems and ideas, his resistance to sale and matters concerned with how he can be influenced and interested.

Competition must be estimated and considered not with the emphasis usually placed upon it, but with some consideration of its intensity in different localities, its territorial influence, and its effect upon the necessities and costs of selling in those particular sections.

Unfortunately, there are no standard methods and there are no fundamental bases laid out for this consideration.

One manufacturer of automobiles has succeeded in making a very good business without using distributors, without a large sales force and branch offices, and without the usual amount of merchandising and advertising effort.

Another concern operating in about the same price class has succeeded with methods diametrically opposed to the first. Out of such apparent contradictions it is difficult to determine the elements of value. Experience does not teach very much under such circumstances. In any case, the teaching of experience is much more largely concerned with showing what to avoid, rather than what to do.

The great strides which have been made in the production of automobiles, trucks and other automotive products are due to the constant and continual investigation and analysis of the engineering and production factors. The most constructive thought, the most careful research and the most definite study have gone into the production of the vehicle, so that this production represents a very large and efficient service of unusual value to the user.

On the other hand, sales executives have been recruited from successful salesmen, forceful and alert men of the speculative type, efficient publicity men and individuals from many other lines. These men have not associated themselves together in the interests of more efficient methods and their practice has been widely different, sometimes contradictory and frequently entirely experimental.

It is not sufficient, therefore, to consider the marketing problem in the automotive field entirely from the practice which obtains in the field at present, nor from

---

**P**ROBLEMS of marketing are absorbing much of the time of manufacturing executives. To decrease the cost of selling a given unit is an important industrial problem. This article marks the beginning of a series of discussions of marketing fundamentals which will appear every other week in AUTOMOTIVE INDUSTRIES. Mr. Tipper's broad, practical experience and his faculty of keen analysis will be brought into these discussions and applied directly to the automotive industry. This first article outlines the present situation and defines the problem.

---

the apparent success of that practice. Without a knowledge of the factors which have made the practice valuable for one organization, such practice would be of little value to some other organization with a different personnel, a different product and a different sales necessity.

These practical methods are interesting and carry valuable suggestions to the man who examines them. A very large part of their value will be lost, however, unless they are analyzed in the light of fundamental marketing necessities and the elements of the sales problem applicable to the particular organization. The failure of the work in merchandising, selling and advertising so far has been due to the lack of fundamental consideration and our ignorance about the relative value of the different factors entering into the problem.

That is why most of the literature on selling, advertising and merchandising is uninteresting and academic.

For some considerable time AUTOMOTIVE INDUSTRIES has been considering this question of dealing with the marketing.

A great deal of work has been done in the consideration of methods of working with the dealer, the distributor and the arrangements for contracting with the various establishments concerned in the distribution of cars and trucks. A good deal has been said about merchandising statistics, and so forth. However, all these things do not touch the root of the matter and they do not illuminate the severe problem facing the manufacturer to-day.

The tendency is for marketing costs, the costs of selling and distribution, to increase with the area covered and the intensity of competition. These costs already absorb too large a percentage of the total price and they tend to absorb a still larger proportion. They must be cut by making the efforts more efficient, so that less expenditure of time and money is required for the unit of sale.

It is appropriate, therefore, to discuss the elements entering into the marketing problem as related to the merchandising of automobiles, trucks, tractors, parts and accessories, to consider the factors entering into the costs, and to suggest the fundamental tendencies governing these factors. By this means the practical applications recorded in this publication will be made of more value and the examinations of practice more definitely serviceable to the manufacturer.

The only purpose of experimentation is to determine the best method of operation. Where experimentation provides nothing more than the basis for further experiment, it is not justified, and its cost is much greater than it should be. A considerable part of the cost of merchandising and selling arises out of the experimental character of the work and the amount of guess work involved. This is not justified, except as we can discover the best methods by the analysis of the experimental practice.

An article that costs \$2 to manufacture must be priced at about \$8 to \$10 to the user in order that the dealer, wholesaler and sales agent, the transportation company, the warehouse, the rehandler and all the other intervening people can be accounted for and the various profits realized along the line.

The manufacturer is intensely interested in the efficiency of the dealer. This is as important to him as the efficiency of his own sales organization.

Every element of marketing which absorbs too much cost increases the sales resistance and limits the purchase of the product. All these elements are worthy of examination and consideration, in the endeavor to determine the process and methods of most value and the fundamentals governing the cost of the merchandising and marketing operations.

In fact, economies must be made along these lines if the market is to be kept to the highest point of activity. Efficiency must be improved. The improvement of efficiency comes about through the increase of knowledge, and that increase is important to the automotive manufacturer at this time.

## Fundamental Photometric Quantities Defined

ENGINEERS connected with the manufacture of vehicle lighting apparatus may be interested in the following definitions of photometric units adopted by the International Commission on Illumination which met in Paris some time ago. The original definitions were in French, and those here given are translations of the French definitions made by the American delegate to the convention. It has been agreed that the final or official English translation shall be one which bears the approval of both the English and American delegates, and it is, therefore, possible that slight changes in wording will be made. The provisional definitions are as follows:

**Luminous flux** is the rate of flow of radiant energy evaluated with reference to visual sensation. Although luminous flux must strictly be defined as above, it may be regarded for practical photometric purposes as an entity, since the rate of flow is for such purposes invariable.

The unit of luminous flux is the lumen. It is equal to the flux emitted in a unit solid angle, by a uniform point source of one international candle.

**Illumination** at any point of a surface is the luminous

flux density at that point, or, when the illumination is uniform, the flux per unit of intercepting area.

The practical unit of illumination is the lux. It is equal to one lumen per square meter, or it is the illumination at the surface of a sphere of one meter radius due to a uniform point source of one international candle placed at its center.

As a consequence of certain recognized usages, the illumination can also be expressed by means of the following units:

Using the centimeter as the unit of length, the unit of illumination is one lumen per square centimeter, and is called the phot. Using the foot as the unit of length, the unit of illumination is one lumen per square foot, and is called the foot-candle.

**The luminous intensity (power) or candle-power** of a point source in any direction is the flux per unit solid angle emitted by the source in that direction. (The flux from any source of dimensions which are negligibly small by comparison with the distance at which it is observed may be treated as if it were emitted from a point.)

The unit of luminous power (intensity) is the international candle, such as has resulted from international agreement between the three national standardizing laboratories\* of France, Great Britain and the United States of America in 1909.

\*These laboratories are the Laboratoire Central d'Electricité, Paris, the National Physical Laboratory, Teddington, and the Bureau of Standards, Washington.

# European Engineering Trends Shown at Paris Show

Overhead valve and detachable cylinder heads seem to be gaining favor among French manufacturers. Unit power plants are also in evidence on most models. Left hand steering taken up slowly, but a few have adopted the American standard. Many other new features were exhibited

By W. F. Bradley

**B**Y reason of the big number of small and medium cars which have been produced this year, the four-cylinder engine is in a greater majority than ever before. Considering Continental makers only, it can be declared that for the normal type of car four cylinders are believed sufficient, and six cylinders meet all requirements when a luxury type is desired. There are a few exceptions. Thus Voisin and Fiat have put on the market twelve-cylinder automobiles. The first of these two represents a personal ideal of Gabriel Voisin, and only in a secondary way reflects the state of the market. Fiat appears to have been guided toward a twelve-cylinder car because the firm has a world-wide market and with its reputation can always sell a limited number of cars built irrespective of price. It is certain, however, that Fiat does not count on this type to keep its big factory occupied.

Talbot-Darracq, De Dion-Bouton and Bellanger retain their eight-cylinder V engines, but these are by no means the most important types in their respective programs. Lancia has added a small angle eight to his line, after having experimented for a long time with a twelve-cylinder of the same general design. A certain amount of interest is being shown in the eight-in-line, for four of these have made their appearance this year, built by Bugatti, Panhard-Levassor, Imperia and Isotta Fraschini. The first named is a special sporting model very closely approaching the pure racing type of car, while the straight eight appears to have been adopted by Panhard as a more satisfactory job from an engineering standpoint than the straight six sleeve valve engine. With these exceptions the "four" dominates for the normal type of car and the "six" holds the high-grade field.

It is worth noting that there is a tendency on the Continent to abandon singles and twins for cycle cars and other very small machines. This is contrary to the English practice, where the two-cylinder opposed engine still has a following for small machines built down to the lowest possible price. The French public asks for a straight four, no matter how small it may be.

## Aluminum Engines Losing in Favor

Aluminum cylinders with steel liners have lost in popularity, the only engine of this type now built in France being the Hispano-Suiza, and Spa the only one made in Italy. Another aviation practice of using forged steel cylinders with sheet steel water jackets has failed to make progress, for this construction is confined to the high-grade six-cylinder Farman. Even on the cheaper makes the preference is for cast iron cylinders on an aluminum crankcase. As an example, Citroen, who makes one of the cheapest cars in the show, has separate castings for cylin-

der block and engine crankcase. The new sleeve valve Voisin has cylinders, crankcase and gearbox in a single iron casting with the shaft carried in two plain bearings. Talbot-Darracq, on their 10 hp. cheap production job, have cast the cylinders and crankcase together, with clutch and gearbox bolted up to it, as in American practice. The same design has been adopted by the Italian Ansaldo Company, on a cheap production job, by Gregoire, Aries and Alva. These are about the only firms of importance, however, having followed this method of construction.

## Overhead Valves More Popular

Overhead valve engines have made progress, the feature in this connection being their adoption by old-established and somewhat conservative firms. Delaunay-Belleville has an entirely new overhead valve six, with operation by pushrods and overhead rockers, the valves being mounted vertically in a detachable head. This firm's system of forced feed lubrication has been extended to the valve gear, the pushrods being hollow, and the oil passing through them to the overhead rockers. Talbot-Darracq has a commercial overhead valve job for the first time; all Hotchkiss models are now made with overhead valves; Lancia has a sporting type overhead valve four, and his eight-cylinder small angle V-engine is also an overhead valve design; Delage is making his sporting six with overhead valves; the Fiat "twelve" has overhead valves with pushrods; the same valve location is used by Lorraine-Dietrich; by Vinot-Deguingand on an engine having the valves in cages and enclosed pushrods; by Leon Bollée, Imperia-Abadal, and Aries with overhead camshaft, by Gregoire, Delaunay-Belleville, Alva and Salmson, with pushrods, and also by a few lesser-known firms, particularly when they specialize on sporting type cars. Even for high class jobs the tendency now is to use a detachable head with a camshaft in the base chamber and pushrods which pass through the cylinder block. The overhead gear being covered by an aluminum housing, everything is inclosed, and it is frequently difficult to tell, from an external examination, whether the camshaft is located in the base chamber or overhead.

An original type of valve operating gear is used on the new six-cylinder Hotchkiss. Instead of a camshaft of the ordinary design, this engine has an overhead eccentric shaft, with short connecting rods having split bearings, which operate forked plates pivoted on a second shaft immediately below the eccentric shaft. The forks are in contact with a steel disc on the extremity of the valve stem. The advantages claimed for this are a greater degree of silence than is possible with the ordinary type of rocker.

1 and 2—A new overhead valve Chenard-Walcker 183 cu. in. engine. 3 and 4—Delaunay-Belleville 10 hp., four cylinder unit power plant with detachable cylinder head and all control parts mounted on engine. 5 and 6 Panhard & Levassor straight eight Knight engine with continuous webs and steering gear mounted on engine. 7 and 8—Hotchkiss six-cylinder engine with detachable head and overhead eccentric shaft, with both magneto and battery ignition

Ballot announced during the show that he would produce a touring car at a commercial price with a 122 cu. in. engine. This is of the overhead valve type, with overhead camshaft and direct operation of the valves, without the use of followers, by a system which, it is declared, avoids side thrust on the valve stem guides.

#### Battery Ignition on New Models

Battery ignition has gained at the expense of the magneto. In the great majority of cases where a new model has been brought out, battery has been preferred, whether the car was a cheap production job or one of the most expensive. Thus Citroen uses Delco ignition, starting and lighting on his new 5 hp. cheap car; Voisin has Delco on the high-grade "twelve"; Fiat has battery ignition of the firm's own design on the most expensive chassis in the show; Itala has adopted an Italian make of generator-battery ignition on a new sleeve valve six it has produced, and the high-class Hotchkiss six has a combination of magneto and Delco, with the Delco distributor used for the magneto. The high-grade six-cylinder Spa has both battery ignition and a Bosch magneto, the two systems being quite distinct. Paulet, with a good class six, designed by M. Michelat, formerly chief engineer to Delage, uses Delco ignition. Ballot is using Delco on his new car with 122 cu. in. engine. On the other hand, Panhard-Levassor, Lancia and Bugatti have adopted the magneto for their new types. Speaking generally, when new models are laid out battery is used in about 80 per cent of these cases. On an existing model the magneto is never dropped in favor of battery ignition. There is a good example of the current tendency in the Talbot-Darracq models. An eight-cylinder produced since the war, and a 10 hp. built this year, have Delco ignition; a four-cylinder continued from pre-war days has magneto ignition. The fact, too, that many of the French factories placed contracts a year and a half to two years ago with magneto companies and did not take deliveries because of inability to live up to the production programs, has helped in a certain measure to arrest the change toward battery ignition.

#### Detachable Cylinder Heads Gaining

The change from fixed to detachable cylinder head is continuing, among the firms taking to this being Delaunay-Belleville, Hotchkiss, Léon Bollée, Fiat twelve-cylinder, Delaunay Clayette. There are two cases of the abandonment of the detachable for the fixed head, these being the Delahaye models and a 16 hp. Talbot-Darracq. At the same time the new overhead valve engine built by this latter firm has detachable head; the model which has been changed is largely sold in England, where, it is declared, the detachable head is not greatly appreciated. Delahaye, after building all models two years ago with detachable heads, in which the valve caps had been retained, in order to facilitate the dismounting of valves, has entirely changed design, and is again using a fixed head. Léon Bollée recesses the head 5 mm. into the cylinder barrels so as to protect the gasket.

#### Cooling Practice

Water circulation by means of pump continues to hold a majority which is very high in the big car class and moderate among the small cars. Apart from Renault, to whom thermo-syphon water circulation is a fundamental principle of car design, the pump is used on about 95 per cent of the cars above 120 cu. in. piston displacement. Below this size, in which class all the cheaper cars are included, thermo-syphon has a strong following. Pressure from clients and dealers in mountainous regions generally enforces the fitting of a pump. Among the conspicuous examples of the abandonment of the water pump on a good

quality car is the Delage 11 hp. Talbot-Darracq, with a new and cheaper model of slightly smaller size than the Delage, fits a water pump. Link-type leather fan belts are in the majority, followed by flat leather belts. There is no use of fabric belts, and it is not the practice to use a single belt for driving two organs. Belt-driven impellers in the water circulating system are not used by Continental makers. On a large percentage of the higher grade cars gear driven fans are used, either with a flexible coupling or a clutch. At least 95 per cent of the fans are cast aluminum with two or three blades. Thermostatic control of the water has made no progress since last year except on a very few costly cars, of which the twelve-cylinder Fiat is one.

#### Unit Power Plants—Continuous Webs

It would be hard to find a new or redesigned model in the show which does not have unit construction of engine and transmission. Among the well-known firms having adopted unit construction for new types are Farman, Itala, Hotchkiss, Voisin, Ballot, Talbot-Darracq, Imperia-Abadal, Delaunay-Belleville 10 hp., Léon Bollée, Delahaye, D. F. P., Delaunay-Clayette. This takes no account of the makers having used this feature for some time. On the small and medium size cars it is customary to attach the power-plant into the chassis by three points. On the small Voisin there are ball and socket connections at the rear of the block and a cylindrical connection at the front. On bigger cars the more general practice is to employ four point attachment to the frame, thus making use of the engine to stiffen the chassis. There is a growing tendency to carry the crankcase webs right up to the frame members, so as to avoid the use of an underpan, or to reduce this to the smallest possible size. On high class cars, generally, the Hispano-Suiza practice is being followed, not only of extending the crankcase webs to the frame members, but of making a tight fit between the bottom of the metal dash and the top of the flywheel housing; thus all the air entering through the radiator must escape laterally through louvers in the engine hood. This gives the clean appearance so much sought after by critical users. Examples are Fiat, Voisin, Delahaye, Imperia-Abadal, and also the Beck, a very original small car, in which this feature is particularly well worked out. Paulet has attained the same object by having a detachable plate between the crankcase hangers, and putting the electric generator and starting motor under this. These parts requiring little attention, there is no loss of accessibility, and a clean unbroken surface is secured from the crankcase to the frame members.

#### Control Members Mounted on Engine

It is also becoming quite a common practice to mount the steering gear and all the control parts on the engine, independently of the frame members. This practice is being followed out not only on the high class models, but also on the cheaper types, makers having been driven to it from the double standpoint of efficiency and cheapness. Two very good examples are the 11-hp. four-cylinder Delage and the 10-hp. Delaunay-Belleville, which are laid out so that the engine and transmission unit carries all its accessories and can be lifted into the frame complete. Even the accelerator pedal is made quite independent of the dash. With this design the steering gear box is bolted to the engine base chamber instead of to the frame members, and the steering column is stayed to the dash, or in some cases to the instrument board. On the six-cylinder Paulet the steering gear box is attached to the engine base chamber and the column secured by ball and socket joints both to the aluminum dash and to the aluminum instrument board.

1—Star-shaped cross member of frame on Hotchkiss six-cylinder chassis, through which torque and driving thrust are transmitted. 2—Flat platform springs on Delaunay-Belleville six-cylinder chassis. 3—Reversed quarter-elliptic spring on 10 hp. Panhard. 4—Gobron suspension combining a pair of quarter-elliptics and a single leaf cantilever. 5—Arrangement of control members on Delaunay-Belleville six-cylinder chassis. 6—Center control on new Italia chassis

Left-hand steering is being taken up rather slowly. It has been adopted by Citroen, Renault and Lorraine-Dietrich for their big production models. Other firms using it are Paulet, Delage, Farman, Delahaye, Ballot. No enthusiasm is being shown by the French public for left drive, and as all the Continental makers have some interest in the British market, they are obliged to lay out their cars for both left and right-hand drive, according to the country to which they will be shipped. This robs them, in a very large measure, of the advantages of left-hand drive, for if the steering is on the right the levers ought also to be on the right. Some makers get over this by moving the steering from left to right, according to demand, and leaving the levers in the center. This is acceptable on the cheaper grade of cars, but is not looked upon with favor by purchasers of costly cars.

### Three-Speed Gear Boxes Increase

The percentage of three-speed gear boxes shows an increase. Makers of the very light type of car have abolished a gear in order to save cost, and on the expensive types it is the high ratio of power to weight which makes a fourth speed unnecessary. The new Talbot-Darracq and the small Voisin are examples of the tendency toward three speeds on light cars; Citroen, Berliet and Lorraine-Dietrich are other cheap cars provided with only three gears. In the powerful and expensive class three gears are used by Fiat, Hispano-Suiza and Voisin. There is a greatly increased use of helically cut gears for constant mesh pinions and for the third combination.

The method of providing for the drive has undergone modifications by reason of changes in the gearset location and in the types of springs. The majority of Continental cars now have central drive, either with a ball head at the front end of the propeller shaft housing, as on all the Fiat models, or with forked arms to a cross frame member or to the rear of the gearbox. Another new example is the six-cylinder Itala. This system of drive has developed to the detriment of the Hotchkiss drive, and has increased with the more general use of cantilever springs. Hotchkiss, among others, has the fork type of central drive on one model and ball head type on another car. Hispano-Suiza abandoned Hotchkiss drive two years ago. Delaunay-Belleville, on the other hand, has taken up Hotchkiss drive on the new 10 hp. car.

On the high-powered models the drive is not taken through the gearbox, but through a heavy cross frame member. This was adopted by Hispano-Suiza two years ago, and is now used on the twelve-cylinder Fiat and the six-cylinder Hotchkiss. On this latter model extreme rigidity is obtained by a star type construction of central cross frame members, the drive being transmitted through the center of this star, and the ends of the cross members giving greater strength for the attachment of the spring shackles and trunnion.

Drive and torque through the springs have been taken up by Delahaye but, speaking generally, this system is only employed to a wide extent on light cars and cycle cars.

### Suspension Practice

Rear suspension by means of cantilevers has not made any progress, for while this type of spring is found on several new cars, a few makers have abandoned it, particularly for their faster models. Voisin is an example, the cantilever being retained by this firm for the normal 18 hp. model, but dropped by them for the sporting type chassis, and not used on either the twelve-cylinder or the cheap small car. The objection raised against the cantilever is the lateral instability of the chassis at high speeds, and it is on this account that Fiat has brought forth a

special arrangement on the new chassis, the second leaf of the spring being extended rearwards to the rear hangers of the frame. Hotchkiss has a device (see cut) by which it is claimed that variable flexibility is obtained. It keeps the spring under tension, so that the car always rides as if it had its full load of passengers. It is claimed that there is a considerable improvement not only as regards comfort of the passengers, but in the stability of the car on the road at speed.

Renault, on his two big six-cylinder cars, uses long, thick-leaf diagonally mounted cantilevers, which are shackled at the rear below the ends of the axle housing, and at the front end to a rigid central cross frame member. This system was adopted two years ago, when the ends of the springs were carried in rollers. It is declared that the present type, with shackled ends and the front anchorage brought very near the center line of the chassis, has proved very satisfactory, particularly as regards the ability of the car to hold to the road at high speeds. The platform type spring appears to be used only on one of the Delaunay-Belleville models and on Scap cars. Bugatti has adopted his special type of quarter-elliptic spring, with the thick end to the rear, and the thin end shackled to the axle, on his new eight-cylinder model. There is a very similar type of spring on the new 10 hp. Panhard-Levassor.

### Chassis Lubrication

Oilless bushings for spring shackles are only just beginning to make their appearance, being used among others by Talbot-Darracq and Delage. The only car shown with a quick action force feed gun with pressure or bayonet attachment for the shackles and other parts, as used so extensively in America, is the Hispano-Suiza. On high-grade cars provision is frequently made for automatic lubrication from the inside of the oscillating spring pad on the rear axle housing, thus doing away with an external lubricator on this much neglected part. While much has been done to eliminate parts requiring external lubrication, by reason of more important changes in design (unit construction of engine and gearbox, enclosed engine accessories, enclosed clutch, brake and change speed mechanism, enclosed propeller shaft drive, etc.), little has been done to improve the lubrication of spring shackle bolts, or parts of the steering gear. For these parts the old-fashioned screw-down greaser is still in general use.

### Fabric Universals Greatly on Increase

The exhibition shows a most pronounced increase in the use of fabric universals. These are most commonly found on the smaller and cheaper models, examples being Citroen, Mathis, Vinot-Deguingand, Talbot-Darracq, D. F. P., Gregoire, Scap, Sigma and Delahaye; on the bigger cars with enclosed propeller shaft there is also a tendency to use a fabric joint at the front end of the drive shaft, particularly when the torque member terminates in a fork attached to a cross frame member or to the gearbox. An example of this is a six-cylinder rotary valve Itala of entirely new design. On a new Vinot-Deguingand car, with Hotchkiss drive, there is not only a fabric universal at the front end of the propeller shaft, but a fabric coupling enclosed within the flywheel, interposed between this member and the clutch. The clutch, a normal type leather faced cone, is external to the flywheel. A somewhat similar idea has been worked out on the Sizaire-Berwick, by the use of studs in rubber bushings, between the flywheel and clutch. Bugatti has made use of fabric as a coupling between the steering gear column and the steering gear worm shaft.

An important change is the use on a big scale of pressed steel welded rear axle housings. Before the war these

1 and 2—Panhard & Levassor 10 hp. Knight engine, the smallest Knight engine ever built. Note steering gear on engine. 3 and 4—Ballot 122 cu. in. overhead valve engine for a new passenger car about to be produced by the Ballot company. 5 and 6—Paulet six-cylinder overhead valve engine, designed by Michelat, formerly Delage engineer. Steering gear on left is mounted on crankchamber. 7 and 8—Delaunay-Belleville overhead valve six-cylinder engine with detachable cylinder heads and tappet rods at side of cylinders

were very rarely employed, but more modern plants has enabled French and other Continental firms to produce this type of axle housing, thus securing greater lightness with increased strength. Those now using this type of axle are Delaunay-Belleville, Delage, De Dion Bouton, Talbot-Darracq, Itala, Berliet. The same general type of axle is used by Fiat, but in this case the two halves of the pressing comprise the axle housing and the propeller shaft housing. There is only a slight use of all aluminum axle housings, the Bignan with steel tube reinforcements being one of these. In the cycle car class there are some examples of all-aluminum axle construction, but this feature has not been extended to full size cars. Bugatti, on his eight-cylinder, has got very light construction by means of a central aluminum housing for the differential and the two gears, with tubular housings for the axle shaft machined out of the solid billet.

Cast aluminum dashes, originally used only on the highest classes of cars, are now common on all models. In the great majority of cases the dash carries nothing more than the vacuum feed tank and acts as a support for the steering column. There is nearly always a separate polished aluminum plate mounted on aluminum brackets, in which the instruments are recessed. Even on low-priced cars of the Mathis class the aluminum dash is frequently found. Among the high-grade makers only a few of the more conservative firms adhere to the wood dash.

### Wheels and Tires

There is not much change so far as wheels are concerned. The detachable wheel, as distinct from the detachable rim, is used everywhere. Renault, Panhard and Talbot-Darracq use detachable wood wheels except for a few special fast models, where the wire wheel is fitted. Fiat is the biggest maker using the Sankey type hollow spoke wheel. This is not a true Sankey, for the hub and the spokes are made of two pressings welded together and then welded to a Michelin rim, whereas the Sankey is a two-piece wheel. The Michelin steel disk wheel is very extensively employed, particularly for the smaller and medium size cars. On very expensive types the wire wheel is a serious competitor.

Straight side tires have not made their appearance, although it was believed one firm would adopt them this year. The clincher bead tire is therefore used exclusively throughout the continent of Europe. Michelin and Bergougnan have both increased the size of their tires for truck service, the largest dimension now made with clincher beads being 1085 by 185 mm. (44 by 7.3 in.).

Both these are cord tires. Tire pumps are confined to high class cars, and are practically always built in with the gearbox, or to be driven off the gearbox. Few of them are now driven off the engine. Paulet has a very neat arrangement, the pump being driven off the gearbox, and the lever for putting it into engagement being on the side of the frame member hidden by a circular sheet metal hinged cover. Inside this cover, wrapping around the control lever, is a length of hose sufficient to reach all the wheels on the car.

Michelin has produced an indicator which notifies when the air pressure falls below a determined figure. This apparatus is only applicable to steel disk and wire wheels. It consists of a valve kept off its seat when the tube is fully inflated, but which drops and explodes a percussion cap when the air pressure drops, thus notifying a fall in pressure whether the wheel is in motion or standing. The indicator can be loaded and fitted with a new cap in a few seconds. Its use is particularly recommended for dual wheels.

### Ballot Now a Car Manufacturer

Ballot entered the Paris show as the manufacturer of a high-grade sporting type car, guaranteed to be an exact duplicate of his 122 cu. in. racing mounts. It was declared that only 100 of these would be built, the chassis selling price being 80,000 francs. For sporting purposes the chassis had been fitted with electric lighting and starting, aluminum dash, aluminum instrument board, special indicators, etc., and the sample chassis were shown with very highly finished two and three-seater sporting bodies.

Before the exhibition closed Ballot announced that he would put on the market a commercial type 122 cu. in. car, which, while being high class, would be sold at a very much lower price than the racing duplicates. Only the engine was exhibited. It is a clean-cut block-cast four-cylinder with detachable head, overhead camshaft and two overhead valves per cylinder mounted vertically in the head. The vertical drive shaft is in the front portion of the cylinder block and operates a cross shaft with the Delco distributor on one end and the water pump on the other. There are no followers between the cams and the valves, the arrangement being a special one which, it is declared, avoids all thrust on the valve guides. The transmission is a unit with the engine and provides four speeds ahead and reverse. The chassis has full floating rear axle with spiral bevel gears, and drive and torque are taken up by the springs. Both left and right-hand steering are being provided for.

## English Gasoline Rail Trucks

TWO interesting, and in some respects novel, petrol engined rail locomotive-trucks embodying the Stro-nach-Dutton patents have been built by Guy Motors, Ltd., in England. Each truck has two engines of 30 hp. each, duplicated radiators, and are of a unique design. They have been built for use in Uganda, where the cost per mile for a light railway is about \$40,000. The cost of the trucks, including the trailer stock and permanent way, is less than \$10,000.

The hauling capacity is 250 tons (British ton 2240 lb.) on the level on low gear and 50 tons at 13 miles an hour on top gear. The front of the tractor rests on a four-wheel bogie with flanged wheels for running on the rails,

but the rear wheels are solid rubber-shod and will run outside the rail track on a prepared smooth surface. Provision exists for replacing the rail bogie and wheels with an ordinary Ackerman steering equipment and rubber-shod road wheels.

The powerplant comprises two 30-hp. (1000 r.p.m.) Guy "four" truck-type engines placed side by side over the driving axle, and driving through a couple of cone clutches and a short flexible shaft to a silent chain reducing gear with a dog clutch interposed, which serves to couple both power sets as a common unit. The drive thence through a shaft and four speeds and reverse gear to double reduction (spur and bevel) axle gears.

# New Earl Car Is Larger Edition of Briscoe

New features are added to the former model, however, and some parts have been changed. The heavier car has called for a more powerful engine. Fittings and trimmings include new appliances and a feature is the design of ignition system enabling operation of all lights with the left hand.

By J. Edward Schipper

**A**S recently announced through AUTOMOTIVE INDUSTRIES, the Briscoe Motor Corp. has been succeeded by Earl Motors, Inc., and the Earl car, a refined and larger edition of the previous Briscoe, is ready for delivery. The factory has recently been refinanced to manufacture, on a minimum basis, 15,000 cars annually. Production at present, however, is not starting on a capacity schedule, although in a recent statement President C. A. Earl said that plans are being made to double this minimum capacity and to aim for a 30,000 schedule in 1922.

The new car is longer and more powerful than the previous product. The wheelbase has been increased from 109 to 112 in., and cylinder dimensions are  $3\frac{7}{16}$  by  $5\frac{1}{4}$  in., as compared with  $3\frac{3}{8}$  by 5 on the previous model. In conformity with the increased weight of the car, the tire size is now 32 by 4 in. (non-skids, all around) in place of the 31 by 4 in.

on the previous product. In mechanical details the car closely resembles the previous Briscoe.

Practically the entire Earl car is manufactured in the Jackson plant, which makes its own engine, transmission gearset, steering gear, front and rear axles. The engine is a four-cylinder, block cast, L-head type with detachable cylinder head, three-bearing crankshaft and four point flexible suspension. This suspension is designed to hold the engine rigid against the torque reaction, but to allow the frame to twist.

The crankshaft diameter has been increased to 2 in. and end thrust is now taken up on the middle of the three bearings by means of flanges. The endplay of the crankshaft is limited to between .002 and .004 in. The attached counter-weights in the former model have been discontinued. The timing gear train comprises steel crankshaft and generator gears and a fabroil camshaft gear with a cast iron center. These gears are cut with helical teeth of 1 in. width of face.

Cooling is by the thermo-syphon system. The hose con-

nections are large, being 2 in. in diameter, and the water jacket on the cylinder is carried below the bottom end of the stroke and all around the valve seats. The capacity of the cooling system is 5 gal. The radiator is located so that its bottom edge is on a level with the bottom of the combustion chamber, which tends to keep the hot water in the top tank of the radiator and the upper half of the core, and the cooler water in the engine.

Fuel is fed from the gasoline tank in the rear and by vacuum to the Scoe 1 in. carbureter.

This is a variable venturi type in which the venturi opening on the carbureter is arranged to adjust itself automatically to the load requirements of the engine, so as to maintain constant air velocity at all engine speeds. The electrical equipment of the car comprises a two-unit Auto-Lite starting and lighting system in connection with Connecticut battery ignition.

The Earl Model "40" Touring Car

The rear axle is semi-floating with differential and drive gears of nickel steel. The standard gear ratio is 4.66 to 1, instead of 4.18 as on the old model. Hyatt bearings are used in the differential and rear wheels and New Departure radial and thrust bearings in the drive pinion assembly.

The frame is a single drop type with 7 in. side bars braced with five cross-members and two gusset plates. The rear springs are 56 in. in length and the front springs are 36 in. All are semi-elliptic. The front wheels are mounted on Timken roller bearings and the front axle is of the drop I-beam type. The steering gear is a worm and gear type mounted on ball bearings provided with adjustment features. The chassis is lubricated by the Alemite system.

In the trimming and fitting work particular care has been employed to bring the new model up-to-date. The windshield, for instance, is of the new one-piece ventilating type with a glass 38 in. wide. It is leakproof in rainy weather, a molded rubber weather strip being fitted over the cowl immediately under the windshield to give a rain-

(Continued on page 816)

# A German Passenger Car of Radical Design

The engine is aft and every possible obstacle on the streamline body is removed to minimize air resistance. A single seat for the driver in the center of the car gives him a clear view of the road. Transmission and differential gear, engine and clutch are combined into unit powerplant.

IT seems a rather late day for introducing a design of car in which the principal components are grouped in an entirely novel manner, now that all of the world's leading makers have practically agreed on one standard form of chassis. Yet it must be admitted that the conventional design is not ideal by any means; that many of its features are subject to more or less serious objection, and that there is a possibility of improvement.

A design intended to overcome some of the acknowledged shortcomings of the present conventional passenger car was exhibited by Dr. Edmund Rumpler at the recent Berlin automobile show. Dr. Rumpler is one of Germany's leading aircraft manufacturers, but he has also had considerable experience in automobile design, having been connected in earlier years in engineering capacities with the Adler and Daimler firms. The principal defects which Dr. Rumpler set himself to overcome by his design are the following:

In the standard car, owing to the great distance of the engine from the drive wheels, the efficiency of transmission is rather low. Because of non-conformity of the chassis and body to streamline shapes, the air resistance at high speed is very great, resulting in a waste of power. The suspension is not as good as it might be and prevents fast driving on poor and indifferent roads. Other minor faults are that the shape of the body is such as to raise annoying dust clouds on roads which are not dust-proofed that the rear seat passengers are subject to unpleasant drafts and that sometimes the driver does not command a sufficiently free view of the road ahead.

As may be seen from the photographs herewith, the body of the Rumpler car is of streamline form, running out into a blunt edge in front and a sharp edge in the rear. The steering post is arranged centrally in front, and the control members are located for right-hand operation by the driver. Floating cantilever springs are fitted both front and rear; but whereas the front springs are arranged parallel to the axis of the car inside the body, the rear springs are placed at an angle to this axis and the rear half protrudes from the body. The front axle is of con-

ventional design, with Ackermann type steering, and extends through openings in the frame. Room for spare wheels is provided inside the body, the wheels being carried horizontally and introduced through suitable openings in the frame members.

A six-cylinder W or fan type engine is fitted, and is located back of the rear seat in a compartment of the body. What may be called the stern of the car, i. e., that portion back of the rear seat, is divided by the radiator into two compartments. In the forward one of these com-

partments, which is covered by the usual bonnet, the engine is located. The bonnet is provided with louvres through which cooling air for the radiator can enter, and the air, after passing through the radiator, leaves the rear compartment through louvres in its wall. Water circulation is by pump, and the air is circulated by a positively driven four-bladed fan.

Engine, clutch, transmission and differential gear with bevel drive are combined into a unit power plant. This whole unit is spring-supported, and only the rear axle

Fig. 1—The Rumpler streamline car

ends, which are independently movable of each other in a vertical plane, are unsprung. Thus the unsprung weight is reduced to a minimum, and the car should be very easy riding. Short, light radius rods connect the ends of the rear axle and the extreme rear end of unit power plant, where there is a spherical joint. There is a service brake at the rear end of the unit power plant and in addition there are emergency brakes on the rear wheels. Front wheel brakes are also fitted, the control being by cable passing through the knuckle pins. The muffler occupies the extreme rear end of the body and the car is completely enclosed underneath by an undershield attaching to the frame and extending from tip to tip.

The engine comprises three pairs of twin-cast cylinders set at angles of 60 deg. with each other. Cylinder dimensions are 74 by 100 mm. (2.91 x 3.94 in.) and the engine develops 36 hp. at 2000 r.p.m. There are four valves in each cylinder head, operated by a short camshaft carrying two cams, which is driven from the crankshaft through helical gears. Each cam operates one inlet and one exhaust

valve, and for closing the valves only two springs (leaf springs) are required.

The two-throw crankshaft is completely balanced by balance weights on each crank arm and is mounted in babbitt bearings. There are master connecting rods for the two central cylinders and swiveled rods for the others. Aluminum alloy pistons are used.

Lubrication is by force feed with dry sump, a feature borrowed from aircraft practice. A small plunger pump draws oil from a tank and forces it into the hollow crankshaft. Through oil holes in the crankshaft and small oil tubes extending up the connecting rod shanks the oil reaches the crankpin and piston pin bearings. The surplus oil accumulates in the crankcase sump, and as soon as a certain level is reached therein a second oil pump begins to work and returns the oil to the tank. The drive of the fan is by gear, with the usual friction clutch.

A sectional view of the power unit is shown herewith and brings out the fact that it is extremely short. There is a multiple-disk-in-oil clutch in the flywheel, with comparatively few disks of rather large diameter. A clutch brake facilitates gear changing. The three-speed gearbox is also unusually short, being rendered so by the fact that there are sliding sets on both the primary and the secondary shaft. The tail shaft of the transmission extends through the center part of the rear axle and carries the differential and the foot brake drum. The arrangement of the bevel gear drive and differential is similar to a design which has been used by Mercedes for the purpose of permitting of arching the axle. Instead of being co-axial with the rear axle, the differential gear is mounted on the driving shaft, and each of its side gears is provided with an elongated hub at the outer end of which there is an integral bevel pinion. Each bevel pinion meshes with a bevel gear on one of the rear axle shafts. The two bevel gears are not of the same pitch diameter, one being sufficiently larger than the other so that its pinion does not interfere with the other gear. Both bevel gear sets have the same ratio, of course. The object of using this design of differential in this case is to permit each axle end to rock independently around the axis of the propeller shaft. In the longitudinal section of the transmission and drive the compact arrangement of the transmission gears will be noted, and it will also be seen that ball bearings are used throughout the transmission and drive. The drum of the transmission brake overhangs its bearing.

Fig. 2—Vertical section through engine

In Fig. 7 will also be seen guide slots in the differential housing above and below the driving gear. These two sections are of the same guide slot, which extends all around the cylindrical differential housing and accommodates two guide shoes into which the inner ends of the axle tubes are fastened. This is clearly shown in the sectional view of the rear axle. The driving shafts are mounted in ball bearings in and on the axle tubes, and the axle tubes and shaft together therefore can swing vertically around the propeller shaft axis, the differential housing being provided with large openings for the purpose on both sides, which are closed by means of leather covers. To brace the axle halves in the horizontal plane, radius rods are run from the ends of the axle tubes to a spherical joint at the rear end of the power plant, as clearly shown in the longitudinal section and the photographic view of the power plant. The result of this mounting is that if one of the rear wheels encounters a road obstruction, only that wheel and its half of the axle are thrown up thereby, the central housing of the axle being spring-supported and not directly subjected to road shocks. It is obvious from the above that the unsprung weight is exceedingly small, and it is claimed that this results in unequal smoothness of riding. This effect is obtained without undue complication and without the use of universal joints. In this design the differential compensates not only for any dif-

Fig. 3—Power plant and rear axle complete. Fig. 4—Connecting rod assembly. Fig. 5—Rear axle with half of casing removed, showing guide shoes. Fig. 6—Three quarter rear view of chassis

ferences in the horizontal travel of the two wheels, but also for any differences in vertical motion.

Fig. 9 shows the arrangement of the front springs, which are completely enclosed by the frame and under-shield. The springs have a spherical mounting at the center on a transverse frame member, and there is a similar connection between spring and frame at the rear end. The front ends of the two springs are pivoted to the front axle, and from the center of this axle an adjustable radius rod with ball joints extends to a frame cross member near the front end of the frame. The frame consists apparently of a single wide channel section, there being a welded joint at the front and a considerable number of cross members, while the muffler joins the two rear ends. Both the main frame channel and the cross members are pressed with large openings, partly to lighten the construction and partly for the passage of control rods and the entrance of the spare wheels. The openings for the spare wheels are closed by pressed steel cover plates.

While the small unsprung weight is a factor tending toward easy riding, the distribution of weight and the arrangement of the seats also influence this factor to a considerable degree. As may be seen from the diagram Fig. 11, in the Rumpler car the passenger seat is located at the center of gravity of the whole car (this center of gravity having been found by taking moments of the weights of the different components in the usual way. In a standard car the center of gravity is usually located at the driver's

seat, which, of course, is not as desirable in a car intended to be driven by a chauffeur. In the Rumpler, however, the driver's seat is also well inside the front axle. From the illustrations it is apparent that the car is of quite low build and that its center of gravity must be low. By taking moments in a vertical plane it has been found that the center of gravity is only  $28\frac{1}{4}$  in. from the ground. The weight is pretty well concentrated between axles, and this results in a low mass moment of inertia around a horizontal axis through the center of gravity. This moment is found by multiplying the weight of each part of the car by the square of its distance from the center of gravity, adding these figures, and then dividing by the acceleration of gravity. A Rumpler open car with driver and four passengers weighs approximately 3000 lb. and has a mass moment of inertia of 780 ft.-lb.-sec.<sup>2</sup>; a closed car with the same number of passengers weighs 3470 lb. and has a mass moment of inertia around a horizontal axis through its center of gravity of 800 ft.-lb.-sec.<sup>2</sup> It is stated that for standard cars carrying the same number of passengers the weights and moments of inertia are for the open type, 4070 lb. and 1485 ft.-lb.-sec.<sup>2</sup> and, for the closed type, 4730 lb. and 1515 ft.-lb.-sec.<sup>2</sup> With a smaller mass moment of inertia, it is stated, if the car body is set in vibration by road inequalities, these vibrations will be damped out more quickly. On the other hand, it would appear that such a body would be set in vibration more easily.

Fig. 10—Front axle end with front wheel brake

Fig. 11—Diagram of weight distribution

The body is of full streamline form, as shown by the photographs, and to obtain this form not only the spare wheels but also the battery and tool box are concealed within the body. No running board is provided, but instead there is a step, which, after having been used, folds up automatically so as to reduce the air resistance. When the door of the car is shut the step disappears in a space provided for it in the side of the body.

In order to minimize air resistance the head lamps are mounted in the front of the body, being held in place by light tension bolts.

A pure streamline body naturally cannot be fitted with the conventional mudguards. Dr. Rumpler uses for his car fin-shaped mudguards of elongated streamline section. Over each front wheel there are two mudguards, arranged one above the other. The larger of these carries at its forward end the built-in side lamp or parking lamp.

The car has a wheelbase of 114 in. and a track of 51 in. It is fitted with 880 x 120 mm. tires all around and is capable of a speed of 56 m.p.h. For long trips a detachable trunk can be fitted over the rear end of the body. The engine is said to be as accessible as in the standard car and the rear axle and transmission more so.

Fig. 12—Headlight mounting.

The principal advantages claimed for this new design are the following: The air resistance is very low, on account of the streamlining of body, underpan and limousine top, as well as enclosed axles, springs, spare wheels and accessories. The mechanical efficiency is high, on account of the absence of a long propeller shaft, torque tube and universal joints (this increased efficiency is probably largely imaginary.—Editor). Comfortable riding and great stability in turning corners, owing to the low center of gravity, small unsprung weight, rational arrangement of seats and proper distribution of weight. The car raises little dust. Passengers are not annoyed by odors and gases from the engine. The driver has an absolutely clear view ahead in crowded traffic. The machine is light and is cheap to produce.

## New Earl Car Is Larger Edition of Briscoe

(Continued from page 811)

tight joint. The top of the open car is provided with a low, clear vision light with French bevel plate glass. By dropping the floorboards below the top of the frame the seats are brought low to the ground, while still leaving them the usual height above the floorboards.

An interesting feature which is found on all models is the design of the ignition switch. It is mounted on the instrument board at the left of the steering column in a separate case within finger reach from the steering wheel. This makes it possible for the driver to control all of the lights on the car with the left hand, leaving the right hand to handle the steering wheel and center control. The headlamps are the new drum type and side lights are provided for parking. A rear view mirror above the windshield and an adjustable sun visor and car heater are included in the equipment for the closed models. The touring car comes in genuine leather upholstery and the sedan and brougham are trimmed in wool broadcloth. The door windows on the closed cars are operated by the new Dura crank type regulator and the interior hardware is of

oxidized silver finish, with a blue enamel design. The road weight of the touring car without passengers is 2550 lb. and that of the sedan, 2800 lb.

The prices of the different models are as follows: Touring car, \$1,285; sedan, \$1,995; brougham, \$1,995; roadster, \$1,375; panel delivery, \$1,160; screen delivery, \$1,085.

THE small car bids fair to remain popular in England for at least another year, although a stabilization of industrial conditions will likely bring about a demand for heavier cars. The Manchester Guardian, in discussing the subject, says the small car, in addition to its relative cheapness, has been found entirely satisfactory to owners. They point to the fact that motoring has become a business and unless the business depression is removed it is unlikely that buyers will want to sink large sums in more expensive machines. However, the Guardian says, once a man becomes a real motorist the demand for more power is apparent.

# British Tractor Trials Develop Interesting Engineering Features

Many farmers attended the exhibitions carried on over 500 acres of land. In addition to the official tests salesmen had opportunities to give demonstrations of their machines to the visitors. American-made machines received favorable comments and a number of new models were introduced.

By M. W. Bourdon

THE question as to whether there is justification in continuing the annual tractor trials—of which the third has, at the moment of writing, just been concluded near Shrewsbury, England—was answered most emphatically in the affirmative by all of the many interested parties on the spot who were interrogated. "Are you satisfied that the time, trouble and cost expended on such organized trials are worth while?" "Do they stimulate sales?" were among the questions put to numerous representatives of British makers, English distributors of imported machines and dealers, while some of the farmers present engaged in conversation promiscuously and casually were asked: "Does this sort of thing appeal to you as a practical and forceful demonstration of the advantages of tractors?" The answers were invariably "Yes."

The only individual heard to suggest that the 1921 British trials could well be the last for five years to come was a member of the staff of an agricultural journal.

Admittedly, the members of the industry who were questioned were only too well alive to the fact that most British farmers are holding tight to their pursestrings this year; in other words, tractor selling in England is now all work and no pay—or very little of the latter. But it is held that of the several ways and means of attempting to get the farmer interested in tractors, to show him what they will do, to enable him to make up his mind which type or size will suit him best, and eventually to make him a buyer, tractor trials run on the lines of those just finished in England are proving as successful as any.

Although the British trials were planned and organized solely by the Agricultural Section of the Society of Motor Manufacturers and Traders in 1919 and this year, and in 1920 in conjunction with the Royal Agricultural Society, the aim has been so to frame the rules and to impose such tests under impartial observation that the official reports issued after each event as to operating costs, work done, speed, etc., shall be above reproach. Further, to avoid the need for awaiting the final and full report before anything definite can be learned on such matters, the organizers this year placarded, at

the administration offices on the ground, tabulated performance results immediately these were ready during the four days over which the trials were spread. These tables accompany this article.

## Scene of the Trials

Plowing and cultivating were carried out this year on 26 fields widely spread in slightly undulating country, the total acreage available being approximately 500, with the largest field some 50 acres in extent. The character of the soil varied very appreciably, and, while there was none which could be described as really light or exceptionally heavy, the latter class was closely

approached — "full three-four horse land," a local farmer termed it. And, what is more, this heavier land had been dried so hard on the surface during the remarkable drought, even now barely broken, that it was exaggeratingly referred to as resembling concrete. "No sane man would attempt to plow it in that state with horses," two farmers remarked to the writer. "If tractors can tackle that, they can tackle anything," said another.

The weather was dry during the trials, and the only case of insufficient adhesion observed occurred with a Renault chain-track machine (Fig. 1) doing six furrows at once on a piece of rising ground. This machine weighs 7270 lb., has a four-cylinder engine, 3.7 x 6.3-in. bore and stroke, and in the drawbar tests gave a sustained pull of 3620 lb., but with a drawbar horsepower of only 14.3. On the same field as this Renault, on the next plot, was the 45-hp. Case (5½ x 6¾ in.), hauling with ease two three-furrow plows of the same size, but set to a depth of 6 in., as compared with the Renault 5 in.

## Scheme of the Trials

In previous British trials the machines have run only under official observation, which means that for quite 50 per cent of the period of the trials they were standing idle. But this year the idea was that every tractor should be at work all the time, so that no matter which day of the four allocated to plowing and cultivating the individual visitor should select to be on the ground, he

Fig. 1—Side view of Renault chain tractor

Fig. 2—Avance tractor with single cylinder semi-Diesel engine

Fig. 3—Rear view of Avance

could, if he wished, see any one or all of them at work. When the machines were not undergoing one or other of the official tests they were demonstrating.

But this plan, though it was adhered to, did not work to full advantage, owing to the wide area covered by the fields available. Grass land is as much in evidence in the district as arable, and as a result it was a physical impossibility for any one man to visit every tractor and give each one due consideration. In future trials it is probable that it will be arranged that on one day all the tractors will be at work in one field or in two or three adjacent inclosures demonstrating pure and simple, the official tests being held on the other days whenever it may be convenient to have them. The day of the concentrated plowing will be advertised in advance, so that the farmer can select that day to visit the trials.

### The Official Tests

With the new Watson drawbar dynamometers available more prolonged, more numerous and more precise tests could be made than in previous years, and certain

factors which have previously been judged by mere opinion or casual measurement were brought out mechanically.

On the Saturday and Monday, preceding the four days on which the public was invited to attend, the machines were weighed and tests of maximum drawbar pull were made; in the latter the dynamometer was interposed in series with the drawbar coupling, while the machine under test hauled one, two, three or four other tractors, the drivers of which applied their brakes if required to impose the necessary load. The results of these tests were posted up on the ground immediately they were concluded (see Table I).

For four days the official plowing tests were conducted, a group of the machines being taken in hand each day until all had been dealt with. At other times they were demonstrating with plows and cultivators. Between whiles, too, each was submitted to a belt pulley test against a water dynamometer outfit rigged up on a heavy truck trailer hitched to a tree.

TABLE I  
Tests of Maximum Drawbar Pull\*

Tractor No.	Name	Speed in feet per minute	Pull to skid wheels, lb.	Sustained pull, lb.	Drawbar, hp.
1	Austin (kerosene)	215	2,000	1,820	11.4
3	Austin (gasoline)	206	1,920	1,720	10.6
5	Blackstone	125	4,060	3,470	13.2
6	20.4 hp. Case	161	2,090	1,710	8.4
8	28.4 hp. Case	167	3,660	2,680	13.6
10	45 hp. Case	152	5,080	4,080	18.8
11	Cletrac	225	2,940	2,650	18.0
13	Fiat	168	3,500	3,000	15.3
15	Fordson	175	1,440	1,235	7.35
17	Glasgow	166	2,900	2,450	12.3
18	28.8 hp. Hart Parr	225	3,110	1,725	16.7
19	17.8 hp. Hart Parr	175	2,150	1,730	8.4
20	International Junior	143	2,200	1,700	7.4
22	Lauson	141	3,160	2,400	10.3
23	Parrett	135	3,480	3,140	12.8
24	Peterboro	157	3,950	3,300	15.7
25	Renault (wheel)	150	2,400	2,040	9.3
26	Renault (chain track)	130	4,840	3,620	14.3
27	Samson	130	1,820	1,500	5.9
29	Saunderson	138	3,080	1,930	7.9
30	Titan	156	3,430	2,760	13.1
32	Twin City	175	3,000	2,470	13.1
33	British Wallis	181	2,750	2,560	14.0
35	Avance	86	2,700	2,450	6.4
36	Fowler	124	2,040	1,690	6.4
39	Service	60	480	410	.75

\*In every case the drawbar pull was limited by adhesion and the nature of the ground, not by engine power.

TABLE II.—BELT TESTS

No.	Tractor	B.hp. at 2200 ft. per min. belt speed.	Max B. hp.
1	Austin (Ker)	23.25	23.75

36	Fowler	19.25	20.0
39	Service	—	(b)
40	Simar	—	6.25(c)

(a) Did not line up in time allowed.

(b) Belt pulley too narrow for test.

(c) Could not attain belt speed of 2200 ft. per min.

Fig. 4—The Simar Rotary tiller. This size, the smallest of three, represented the new system of tillage

In the latter test the tractors, with their pulley shafts at right angles to the longitudinal center line of the machines, showed up to great advantage over those having the pulley shaft longitudinally arranged. The Parrett, for example, was called forward, got in position, had the belt mounted and was under test in approximately three minutes, where the Avance (a Swedish tractor), with its pulley at the front end of the longitudinal crankshaft (Figs. 2 and 3), was nearly half an hour before matters were satisfactorily arranged, with crowbars applied under the wheels to supplement engine power in maneuvering. The results of these belt tests were also posted up as they became available (see Table II).

#### Fuel Consumption, Speed and Drawbar Pull

Reverting to the plowing tests, an official observer was appointed to each machine (in each case he was the representative of another tractor maker) and it was his duty to take precise records of fuel and water consumption, the tanks and radiators being drained as a preliminary and the surplus from the replenishment measured at the conclusion of the test. Observers also recorded the area of the land plowed, duration and cause of each involuntary stop, minimum width of headland required for turning and number of attendants required for plowing. The recording dynamometers dealt with the drawbar pull, depth of furrow, distance covered and time occupied, and all these factors will be covered in the complete official report.

But, while to the technical mind the tabulated reports alone will be sufficient to enable the relative merits of the tractors' performances to be realized, the farmer would probably be mystified by them, and if he drew any conclusions at all might do an injustice to certain machines. He might look at the "fuel per acre" column of Table III only, and not realize that the varying resistance of the land and the difference in gradients of the fields might affect adversely or favorably the showing of the individual machine. It is the intention, therefore, that the final report shall make these matters clear, and the results will be made available in such form that direct comparisons can be made.

Coming back to the usefulness of the trials to the industry, there can be no question but that the average farmer was impressed by the thoroughness of the organization and tests apparent at Shrewsbury. The visitor could not fail to observe the signs indicating that a number of tractor makers have sufficient confidence in their machines to submit them for trial to a body com-

Fig. 5—Service hand tractor at work

prising their own trade rivals and willing to have the results of the tests published broadcast.

#### Engineering Features at the Trials

Thirty-eight of the 40 machines entered by their makers or distributors were submitted for trial and these represented 27 models of 23 makes. Of these 23 makes only five had engines other than automobile types, viz., Blackstone and Saunderson (British), Avance (Swedish) and Titan and Hart Parr (American).

The Blackstone has a three-cylinder motor with low-tension ignition, pressure feed for fuel injected into the combustion chamber and compressed air for starting and diluting the charge. This design appeared to be impractical for an agricultural engine, with its high-pressure air container, valves and intricate and fragile valve gear. Its principal merit is that it self-starts on kerosene from cold. The machine is of the chain-track type, with certain peculiar but not pronouncedly advantageous features. It has appeared in three trials in succession and has been taken up by a combine of agricultural engineers.

The Saunderson engine is a two-cylinder plant made by De Dion, and the tractor itself has a good following among those who favor a heavier and slower speed motor than the automobile type. It does not make an impressive showing alongside the majority of other ma-

TABLE III.—PLOUGHING TESTS

No.	Name	Maximum Pull	Average Pull	Depth in.	Acres per hr.	Fuel br. Acre pts.	Fuel used

40	Simar (4)	.....	.....	4	.19	25.6	Gas.

1. These machines hauled two 3-furrow plows.

2. These machines had plots of awkward shape causing loss at headlands.

3. Self-contained motor plow.

4. Garden cultivators, operator walking behind.

Fig. 6—A general view of the field tests with three machines at work

chines in the field, and in general efficiency it is probably lower. But it is a substantial general purpose tractor, with winding drum, and has a good name for durability after being on the market for at least ten years.

#### The Swedish Avance Machine

The Titan and Hart Parr are, of course, well known to readers of *AUTOMOTIVE INDUSTRIES*, but the Avance strikes a new note in tractor design. It has a semi-Diesel, single-cylinder engine of 6.85 x 7.32-in. bore and stroke, which, as usual with this type of engine, is reversible and eliminates the need for reverse gearing—though in maneuvering the waiting for the engine almost to stop before it can be reversed occupies more time than slipping in a reversing gear. There are also several unusual features in the general design. The ordinary type of radiator, for example, is displaced by a cylindrical cooler wherein the pumped water is caused to trickle over the surface of a coil of gauze, spiral in plan, while air is circulated through and around it by a fan at the front (Fig. 8).

Then, again, the Avance can be used either as a self-contained plow or as a tractor with separate implements, but the shares of the attached plow were soon found to be unsuited to the land where this machine was set to work, and it was therefore taken off and a two-furrow separate implement was hauled. The drawbar pull from this tractor is exerted through two long and heavy helical springs under the engine, and these springs are compressed unduly if the plowshares meet with an unusual obstacle in the soil—a tree root or big stone, for instance—and by means of coupling rods and levers the engine clutch is then disengaged, thus bringing the machine to a standstill and preventing damage to the plows.

The general design of the Avance does not strike one as being entirely practical. Its center of gravity is obviously too high and its front wheels unusually small in diameter. Incidentally, its rear wheels are of unequal size, that on the right being 54 in. in diameter as compared with the 48 in. of the other, in order to keep the engine approximately vertical when the right-hand wheels run in the furrow.

The desirability of using a semi-Diesel type engine in agricultural tractors is a matter of opinion. It has points in its favor and seems to appeal to those people who incline toward a slow-speed engine; at Shrewsbury the Avance ran on crude mineral oil in the tests and subsequently demonstrated with palm oil as a fuel. Its exhaust was by no means invisible with either, and it was inclined to misfire somewhat erratically even when pulling steadily under load—though, of course, this

shortcoming is not a necessary accompaniment of the semi-Diesel system.

#### Simar Rotary Tiller

Another newcomer to British trials was the Simar Rotary Tiller, a Swiss production in which tines or hooks of round section spring steel are rotated and provide a fine tilth—resembling that resulting from the use of plow and harrows. It is claimed that an equally good seed bed is thus provided at one operation instead of three or more, and, while as a disturber of the soil the machine is remarkably efficient, this system of tillage does not meet with universal approval from agriculturists, though it is highly spoken of by some users; it does not bury the stubble and weeds as completely as a plow, but merely disturbs them, some being buried, while the remainder lie scattered about half in or out of the soil.

This type of machine is made in three sizes, the two largest being termed 25 hp. and 40 hp. respectively, and having three wheels, but the front one is merely a castor wheel, steering being accomplished by declutching one or other of the rear ones. These two machines are comparable with tractors or self-contained motor plows of similar power, but unfortunately they were not at Shrewsbury, the system being represented by the smallest type, which is hand-controlled and steered by its attendant walking behind (Fig. 4). It is a model intended for use on vegetable farms, orchards and other plantations where its narrow track (22-in. wheel centers, with a maximum of 28 in. of the rotary tiller drum) makes an appeal. It has a two-cylinder Vee engine of approximately 3¼ x 3¾-in. bore and stroke, and on medium land at the trials it steadily tackled a "furrow" of 28 x 8 in., a performance which demonstrated its superior efficiency in a mechanical sense to that of a plow, for obviously an engine developing but 7 hp. at 1200 r.p.m. would not suffice for a two-furrow, 14 x 8-in. normal plowing outfit. Wheel adhesion, incidentally, is quite remarkable, for it is enhanced by the fact that the tines assist to haul along the machine as a whole.

Another "hand" tractor at the trials was a single-cylinder outfit with a single-furrow plow attachment, the Service; but it was out of its element in big fields and heavy land, being, like the small Simar, intended for garden and plantation use in light soil.

No other new tractors were present and some of the old ones seen at previous trials were absent. Among the latter were certain machines of American manufacture—Moline, Chase, E. B. and G. O.—but the United States was represented by the following: Case (three

Fig. 7—Drawing shows the Saunderson shock absorbing drawbar coupling with provision for lateral adjustment. Fig. 8—Advance water cooler displacing usual type of radiator. Fig. 9—Peterboro controls. Note raised "gate" for spherically pivoted gear shift lever. Fig. 10—Glasgow adjustable drawbar. Fig. 11—Saunderson spring buffer for front swivel axes. Fig. 12—Austin flexible front suspension of power unit on axle. Fig. 13—Austin direct drive fan

models), Cletrac, Fordson, Hart Parr (two models), International Junior, Titan, Lauson, Parrett; Samson and Twin City, while the British Wallis also exemplified American design; entirely British machines were the Austin, Blackstone, Glasgow (Continental engine), Saunderson, Peterboro, Fowler (Waukeska engine) and Service. Fiat (Italy) and Renault (France) each had two machines at work.

As regards general engineering tendencies, there were few changes of note. Both gasoline and kerosene were used as fuel, and Austin had two machines running on the one and two on the other. The Austin vaporizing system for the heavier fuel consists merely of a com-

bined inlet and exhaust manifold with a Zenith carbureter, the contact between inlet and exhaust branches being complete throughout their length alongside the cylinder block. This system appeared to serve quite efficiently, gave a clean exhaust, and in the tests of maximum drawbar pull the kerosene-fed machine actually showed better results than the other.

Only one three-wheeled tractor was present, the Glasgow, with its all-wheel drive. For some reason or other this machine has not made the headway in output and sales which was expected of it, but possibly this is accounted for to a certain extent by production delays not making it available in quantities until the slump

commenced. It is still looked upon, nevertheless, as a type which will survive, despite the gradual disappearance of other three-wheelers. Contrary to expectation, by the way, this tractor, notwithstanding its three driving wheels, was limited as to its drawbar pull by lack of adhesion, not by engine power. But in this case, as in many if not all the others, the soil was actually too dry to enable the machines to show up to best advantage. The field where the maximum drawbar pull tests were made was stubble on fairly light soil and kicked up almost as readily as road grit 6 in. deep; even the chain-track machines suffered in performance for this reason.

One of the Hart Parr tractors used a front axle extension to enable the right front wheel to run in the furrow while the other three ran on the unplowed land, and this arrangement seemed to appeal quite strongly to

many of the farmers present. Those of the latter who work heavy land with a clay-like subsoil object strenuously to the two wheels on one side running in the furrow, because of the compression of the subsoil which then occurs, tending to cause the land to become waterlogged, especially when two-furrow plows are used. But they object, also, to running all wheels on the unplowed land, because of the need for the driver constantly to be on the alert for steering. Thus the Hart Parr arrangement appealed as a good compromise, causing but a small proportion of the weight to be imposed on the subsoil and providing something approaching a self-steering effect. The Cletrac self-steering arm also gained approval for a similar reason, but no British maker had any feature of this nature, and all the four-wheeled machines of home production ran with two wheels in the furrow.

## Rate of Penetration in Case Hardening

**I**N the cementation process direct contact between the iron and the powdered charcoal is essential. According to Le Chatelier and Bonnerot no cementation takes place in the absence of any gases in a vacuum, while Guillet and Griffiths obtained some penetration in a vacuum when the charcoal was pressed against the iron. Iris Runge, who has been investigating the problem at Göttingen, believes with Giolitti and Astorri, that gases play an important part in the penetration, but that solid penetration is also possible. In order to study the rate of diffusion of carbon into iron, she had to work with carbonaceous gases. While Giolitti had in similar researches analyzed the successive layers of an iron wire heated in a carbonaceous gas, Iris Runge relies on the increase of the electric resistance of the wire and on microscopical examination. She makes the assumption that the increase in resistance will be proportional to the amount of carbon absorbed by the iron; the assumption is somewhat questionable, but seems justified by her experiments, especially considering that iron does not, under her experimental conditions, take up more than 1.5 per cent. of carbon at near 1000 deg. C.

The wires used in the experiment were 0.5 cm. length, 50 cm. or 25 cm. long, wound to a spiral of 2.5 cm. length, and enclosed in an electric furnace. By copper leads, 2 mm. in diam., the wires were led to a Wheatstone bridge for resistance measurements accurate to 0.001 ohm., and taken every few minutes. The wires, mostly electrolytic iron, were first heated in a current of hydrogen or nitrogen until the furnace temperature and the resistance had become constant; this took about two hours, during which the resistance rose to about ten times its original value. The current of the respective gas was then turned on; the gases tried were: coal gas, as such or diluted with hydrogen or nitrogen; vapors of hexane, benzol, toluene, petroleum ether and methyl-alcohol, likewise diluted. The change in resistance observed would of course partly be a temperature effect. Sometimes a change in resistance was noticed, attributable to carbon; when there was a change, the wire would mostly be covered with loose sooty carbon; this was especially noticed with hexane, and was last noticeable with toluene. When there was no change in the resistance, little or no carbon would be found in the iron on subsequent examination. It was clear that the presence of hydrogen facilitated the penetration of carbon into iron, though the results were not very concordant. The rise of the resistance was generally rapid at first; within about forty minutes constant conditions would be attained. The absorption of 1 per cent. of carbon in-

creased the resistance of the iron at 920 deg. C. by 5.7 per cent., at 830 deg. by 7 per cent., at 18 deg. by 40 per cent., the increase being reckoned on the corresponding temperature. The diffusion co-efficient at 930 deg. C. was  $2 \times 10^{-7}$  sq. cm. per second, and with an active gas 0.6 mg. of carbon passed through 1 sq. cm. of iron surface in the first three minutes. There was no appreciable cementation below 700 deg., and the rate of cementation rapidly rose at higher temperature. The mixed crystals formed above 900 deg. consisted of cementite and pearlite.

## Saving in Shipping Costs

**T**RANSPORTATION is one of the big factors that enters into the purchase price of a motor truck. Especially is this true of cars that are shipped for export. The Royal Rex Motors Co. of Chicago has designed all its truck models so that they can be knocked down and shipped in separate parts. The saving claimed by this method is well over 100 per cent on all shipments to foreign ports. The truck, once it reaches its destination, can be uncrated and assembled by two mechanics in four hours' time.

As an example company officials said the cost of shipping a truck from Chicago to Liverpool, under the old method, was \$250.75, divided as follows: Chicago to New York, \$58.75; New York to Liverpool, \$192. Under the new method a saving of \$155.75 is claimed. The cost from Chicago to New York was given as \$47 and from New York to Liverpool, \$48.

Shipments to other European ports and to South American and Pacific points were also shown to have been made with similar savings.

Crated for shipping

# The Manufacture and Assembly of a Cork Insert Disk Clutch

A description of machining and assembly operations on Hudson and Essex clutches. Most of the parts used in the two clutches are identical and the two are assembled simultaneously in the same department.

By J. Edward Schipper

**F**OR about eleven years the Hudson Motor Car Co. has been using a multiple disk clutch with cork inserts running in oil. This clutch has proven so satisfactory during this length of time that it has undergone but little change. The clutch used in the Essex car is identical with that in the Hudson except that there are two less disks and four springs instead of eight.

A sectional view of the clutch is shown in Fig. 1. The clutch is housed in the flywheel and inclosed by a clutch cover. The drive is transmitted from the flywheel to the driving set of disks by five pins which are riveted to the clutch cover. These pins pilot or seat in holes in the flywheel. From the driving disks, which are provided with cork inserts, the torque is transmitted to the driven disks by frictional contact. Frictional contact is maintained by four clutch springs in the Essex and eight clutch springs in the Hudson, which squeeze the disks together between the clutch drum, which carries the driven disks, and the pressure plate. The clutch is released by forcing pressure plate back against the spring pressure. The actual disengagement of the disks is effected by separator springs placed between them.

The principal units in this clutch, which is manufactured almost entirely in the Hudson plant, are the hub, the cover, pressure plate, disks and spider. The clutch hub is a drop forging, the blank being in solid form roughly flanged to shape. The machining operations on this part are not unusual, consisting of simply drilling the center bore on a Foote-Burt radial and reaming the hole on the same machine, Fig. 2. The hole which is  $1\frac{1}{4}$  in. diameter is then broached to size on a Lapointe broacher. A keyway is also broached in this hole on the same machine. The hub is turned and faced on a Fay automatic lathe capable of turning 12 hubs per hr. These

are turned down to a diameter of 1.8125 in. nominally, which leaves .020 in. for finish grinding. The work is held on an arbor which is pressed into the hub before it is mounted in the Fay lathe, this arbor providing the centers for the operations.

After the  $1\frac{1}{4}$ -in. center hole is chamfered, the holes are drilled for the tapered pins which fasten the hub to the transmission shaft. This is the pin shown at A in the section of the clutch, Fig. 1. Clearance for the nut which is screwed on the end of this pin is milled on a LeBlanc miller, after which eight  $21/64$  in. holes are drilled in the hub flange. Location for this drilling is from the keyway in the broached hole through the center. Two draw holes are then drilled in the flange for puller screws used in removing the clutch. The eight holes in the flange are then chamfered and all ten holes are tapped on a Garvin tapper. The hub is then ground to size and face flanged. This grinding is done on a Norton grinder, the hub being pressed on an arbor and centered, Fig. 3. The final operation on the hub is filing to remove any burr from the keyway.

The clutch cover is a stamping, the only machine operation necessary on this being to grind off the face

on a Blanchard grinder, Fig. 4. This assures a good seating contact with the face of the flywheel against which this cover bolts.

The clutch plates are stampings, the plates containing the cork insert having the holes punched in the plates. The plates which carry the cork inserts are ground on both sides. The pressure plate is only ground on one side, as it has contact only on the side which is drawn up against the contacting disk. The grinding of the plates is done on Blanchard grinders, the plates being held by magnetic chucks. The punched holes in the disks into which the corks are placed are counter-sunk on a Sipp

Fig. 9—Automatic riveter which rivets the driving pins to the clutch cover. Fig. 10—Straightening clutch plates to within .010 in. limit by peening.

Fig. 11—Starting clutch assembly on four pins mounted in assembling fixture. Fig. 12—Clutch about one-half assembled, showing the pressure plate, some of the disks and the separator and silencing springs between them. Fig. 13—Final operation in the clutch assembly, putting the nuts on the ends of the pressure plate studs. These nuts are locked by means of cotter pins

radial so that, in assembling, the corks will not be damaged in pressing them into the holes. The plates are then straightened by hand, this being a peening operation. The corks are put in the disks on an automatic machine which has been specially designed and made by the Hudson company, Fig. 5. The machine has a centrifugal hopper which throws the corks into a feeding slot from which they are forced into the proper holes by means of the feed punch.

The clutch disk is rotated on an automatic indexing machine which always brings a hole in front of the punch in the proper position to fit the cork in place. The corks are soaked in soap and water for a considerable length of time before they are fed into the machine. The final operation on the cork disks is to pass them through a straddle slicing machine, Fig. 6, which slices off the corks on both sides of the disks at the same time. The slicing machine leaves a slight amount of cork projecting on each side of the disk so that even when the clutch is engaged under pressure, there is no metal to metal contact.

The clutch spider is a malleable casting. This spider carries the studs and also acts as the clutch spring retainer. Disengagement of the clutch is secured by moving this spider inward, which, in turn, depresses the clutch springs, allowing the plates to become free to disengage. The spider is bored and reamed on a Pratt & Whitney, the center hole being reamed to 1.8125 in. in diameter, Fig. 7. The location for this is from the outside diameter. This same machine also faces the bosses for the studs. A Warner & Swasey turns the outside diameter, location for this being from the inside bore by means of a roller pilot. The holes for the studs are drilled and then spot-faced on both sides. This work is handled by a three-spindle Sipp, Fig. 8. Grinding the hub to an outside diameter of 2.163 in. on a Norton grinder finishes the operations on this part.

The drum, being die-cast aluminum, requires no machining, except a small operation which is described under assembly.

The cast iron clutch retainer requires some work on a Pratt & Whitney machine consisting of facing off the

ends and boring, reaming, facing and turning the outside diameter. The throw-out pad on the retainer is also milled. The clutch studs are ground to .482 in. with a tolerance of plus or minus .0005 in. on a Norton grinder.

Before the clutch reaches the final assembly bench, there are a number of sub-assemblies made. The annular throw-out bearing is pressed into the retainer and the clutch spider is pressed into the bearing. After this has been done, the spider is finish reamed by hand to secure an accurate inner bore. The sub-assembly is then given a gasoline wash. The oil ring is assembled to the clutch cover, this ring being spun into the cover. The four driving pins which transmit the drive from the flywheel to the driving disks are riveted on the clutch cover on an automatic riveter, Fig. 9. The four pins which transmit the thrust of the clutch spider to the pressure plate on disengaging the clutch are riveted to the pressure plate on the automatic riveter and the pins and plate straightened on a fixture which is so arranged that the pins drop into holes on the fixture, permitting of proper alignment. The pressure plate is polished against emery cloth on a lathe.

The clutch drum, which is an aluminum die casting, is reamed to properly size the center hole and then broached. The jaw liners, which take the wear instead of the aluminum drum itself, are assembled in place and the drum is assembled to the hub with six bolts held in place by locking wire. Before assembly, all of the disks are straightened by peening operations to within .010 in. limits, Fig. 10.

In the final assembly, the clutch is built up on a fixture. The four pins are set up in the fixture and the pressure plate put in place, Fig. 11. The disks are then placed on with the silencing and separator spring placed between them, the disks being placed alternately, first, cork insert and then plain, Fig. 12. The drum and hub assembly is then put in place and the four clutch spring retainers inserted. These are cup shaped stampings which fit into the drum. The four clutch springs for the Essex clutch are then inserted and the spider assembly put over the springs. By means of a nut on the fixture, the spider assembly is

screwed down forcing the springs into the spring retainer. The nuts are then put on the pressure plate studs, Fig. 13, which project through the center of the springs into the spider, and the cotter keys are placed in the castellated nuts. The four clutch cover springs and the four spacers are then put on and the cover is put over the assembly.

It takes a good operator about 6 min. to assemble an Essex clutch and 8 min. for a Hudson clutch. The Hudson clutch takes longer on account of the additional disks and springs. The gang-work system is used on the assembly of these clutches, and owing to the similarity of the work, the same gang can work interchangeably on Essex or Hudson clutches.

Two clutches for two quite different cars come through the same plant and are assembled at the same bench by the same men. It will be asked, no doubt, whether or not this is a good policy from a manufacturing standpoint. This same principle is carried throughout the Hudson and Essex plant, which is combined into one unit at the present time.

It will be remembered that originally the Essex was to have been manufactured in a separate plant, and when normal times are again reached and steady production possible, this may be done. At the present time, however, the fluctuating manufacturing schedules to which all car manufacturers have been subjected have made this plan of

the Hudson and Essex company one possessing some great advantages. In the first place, it has been possible, by alternating the work on the Hudson and Essex through some of the departments where fluctuating schedules had the greatest effect, to maintain a steadiness in the personnel as well as in the machine work which would otherwise have been impossible. This is particularly true in a department such as this clutch department where the difference between the two clutches is so slight. The man who is accustomed to the Hudson clutch has no trouble whatever in doing other work on an Essex clutch, in the few minor instances where the two clutches are different. Even in the assembly work, it would be perfectly possible for a man to assemble first a Hudson clutch and then an Essex clutch without in any way becoming confused or making errors.

In the layout of the clutch department, the manufacturing operations are grouped around the assembly and the entire department is featured by the small amount of movement of parts necessary in completing the work. A square in the manufacturing establishment, roughly, 75 ft. each side, would be nearly sufficient to inclose the entire manufacturing and assembly department for both the Hudson and Essex clutch. This compactness and resultant economy in overhead on the two clutches has advantages which are apparent on the surface.

## Requirements for Successful Piston Castings

**T**HERE are a number of kinks in the manufacture of successful pistons which a specialist in this line of work must soon come to recognize. As specialists in this line of work the McLough Foundry has found that in order to get the best results in the machine shop and to minimize losses there are some definite precautions to take. The following ten requirements are important from the standpoint of successful pistons:

1. Pistons must be soft iron, easily machined.
2. Must be close grained and tight.
3. Must be free from hard spots.
4. Must be free from cracks.
5. Must be free from sand holes.
6. Must be free from sulphur holes.
7. Must be free from cold shut.
8. Must be free from shrink.
9. Must be perfectly round and balanced.
10. Must be strong and tough.

The answers to these ten problems are as follows:

1. A high silicon iron is necessary with correct proportion of sulphur and other ingredients.
2. A mixture of steel is used.
3. The silicon must be not too high and steel and manganese in perfect control.
4. Spiegeleisen and manganese help to strengthen the iron and prevent cracks.
5. Clean molding and perfect cores are necessary.
6. Sulphur content should be low.
7. Hot iron and perfectly tempered sand are necessary.
8. Shrink can be controlled by proper mixture of iron.
9. High silicon is necessary in producing machinable iron. Low sulphur is necessary, as too much sulphur is the worst enemy in the foundry, as it causes hard castings, holes and sponginess. This content should always be under perfect control and closely watched.

Manganese is a natural scavenger and has a natural affinity for sulphur, therefore should be kept well up toward 1 per cent, as it also toughens the iron. Steel is necessary to close the grain of iron, keeping it tight. Up to a certain per cent steel is a softener.

10. The chemical analysis for pistons should analyze between the following percentages:

Silicon, 1.80 to 2.25; manganese, .60 to .80; phosphorus, .40 to .45; sulphur, under .09.

This can be obtained from mixture of following iron:

Pickands Mather Co., Charcoal Iron Pile No. 1—Silicon, 2.90; manganese, .67; phosphorus, .185; sulphur, .03.

M. A. Hanna Co., Silvery Iron Pile No. 2—Silicon, 8.30; manganese, .34; phosphorus, .264; sulphur, .02.

Rogers Brown Co., Charcoal Iron Pile No. 3—Silicon, 2.26; manganese, .59; phosphorus, .178; sulphur, .014.

Mathew Addy, Princess Pile No. 4—Silicon, 1.86; manganese, .832; phosphorus, .438; sulphur, .019.

Spiegeleisen—Silicon, .75; manganese, 18 to 22 per cent; phosphorus, 10; sulphur.

Automobile Scrap (average analysis)—Silicon, 2.00; manganese, .50; phosphorus, .45; sulphur, .12, dangerous.

Steel Scrap (average analysis)—Silicon; manganese, .50; phosphorus, .08; sulphur, .08. Furnace charge of 1500 lb.

Pile 1.....	300 lb.
Pile 2.....	150 lb.
Pile 4.....	150 lb.
Automobile Scrap.....	750 lb.
Steel Scrap.....	150 lb.
Spiegeleisen .....	25 lb.

Total .....1525 lb.

If this mixture is closely adhered to, successful pistons will result, with a foundry loss of about 5 per cent.

Great care should be placed in the making of cores and of molding to keep losses down.

**T**HE recent action of the National Automobile Chamber of Commerce in declaring a pintle hook to be part of the standard equipment of a truck or part of a complete truck, recalls the fact that the S. A. E. has a recommended practice on trailer hitches and this embodies a pintle hook for trucks.

# Motor Bus and Motor Coach Transportation in the British Isles

Automotive vehicles are successfully competing with the British railroads and tramways in both short and long haul passenger traffic. Facts and figures gained in a study of these systems made by an American railway engineer make it apparent that our vehicle manufacturers can profitably investigate the domestic market for large passenger-carrying vehicles.

By Walter Jackson\*

**T**HE recent appearance in Great Britain of Volume 1 of "T. B. R." (Travel by Road) marked the fact that the motor bus and motor coach have attained such importance as to require a national monthly route and time-table guide. From now on every newsstand in the United Kingdom will apprise the public that they can travel from almost anywhere to almost anywhere via tire instead of rail. The first issue of the guide lists 1876 routes; this is far from complete, as a number of important operators have not yet co-operated in its compilation.

The motor bus and sight-seeing car of Great Britain have a long and respectable lineage. The earlier coming of good roads there and the fact that many localities were not so abundantly served with rail service as here led to automotive passenger transport at a time when we had no thought of applying gasoline to public utility vehicles. Of great importance in the evolution of high-grade designs was the fact that the development was in the hands of companies doing business with specifically public utility vehicles, and not in the hands of individual jitney operators, ready to run anything that will move.

The strongest impulse to turn out an economical, reliable motor bus was furnished by the tempting traffic prize of London. Following the days of the horse bus a great variety of types were tried by a large number of competing companies. To-day one concern, the London General Omnibus Company, operates by far the greatest part of the buses used and the remainder is supplied by companies with which the L. G. O. has friendly agreements.

## A 3000-Bus Concern

So many erroneous statements have appeared about the importance of motor buses in the London transport scheme that it may be well here to summarize the position as it really is:

\*Consulting electric railway engineer, formerly editor the *Electric Railway Journal*.

Taking relative use first, we find that in the year 1919, according to figures submitted to Parliament by the Advisory Committee on London Traffic, there were carried 659,000,000 passengers on local underground and other intra-city railroads, 861,000,000 passengers on motor buses and 1,053,000,000 on street railways. There were also carried 468,000,000 passengers (estimated) on the suburban lines of the trunk line railroads entering

London. From this it will be seen that the motor bus stood ahead of the local underground lines, but not of the tramways. A cause of confusion has been that the returns of the great London Traffic Combine (underground, bus and some suburban tramways) under the direction of Lord Ashfield have been mistaken for a return of all London traffic. In the case of the Combine, it is a fact that of the 1,171,701,868 passengers carried in 1920 (exclusive of street railways), 767,953,649 were transported on motor buses. When we take the associated bus routes into consideration, it is safe to say that London's buses now carry about one billion

passengers a year. This should be honor enough!

Second to consider is the fact that London's layout has been exceptionally stimulating for motor bus operation. Because of many narrow and winding streets, the street railway is almost completely shut off from the old cities of Westminster and London, which are the richest sources of traffic. In this area the buses have no competition except from underground railways under the same management. Since the buses, as a traffic proposition, could not very well confine themselves to dropping or taking on passengers at the boundaries of the business and shopping area, the routes have been extended from year to year, until to-day they not only traverse every part of London but go well beyond it. In a number of instances the bus route extends only from the rapid transit terminal outward, but the passenger usually can go in town all the way by bus if he cares to transfer to another route. Many patrons use the bus for the short rides to and from underground stations,

a species of traffic which is encouraged by the use of fares graduated according to distance traveled.

The operations of London bus companies range all the way from the short-haul pick-up service in the congested district to all-day sightseeing country runs with guide and meals included. At present some 2700 motor buses a day are in daily operation, the maximum being reached on Saturday and Sunday. An important change in capacity has been necessitated by the great wage increases of recent years. The 34-seat, Type B bus is being superseded by the 46-seat Type K, of which more than 1000 have been built, and a still bigger bus, the 54-seat, Type S, is in use on certain routes—265 having been put in use in July, 1921. All London buses are made by the allied Associated Equipment Company (A. E. C.).

While the term "supplementary" is hardly adequate to describe a transport system of L. G. O. dimensions, it would be proper to refer to it as being frequently an "alternative" method of transportation. Thus, since no standing is permitted in the new "K" and "S" buses, there are times when a certain amount of traffic is diverted to the same management's underground lines, or in competitive districts the street car will be used. Also, in inclement weather many bus-riders failing to obtain inside seats will ride all or most of the way underground or by street car. The fact that other British cities operating buses lack alternative transport accounts for the general preference of the provinces for single-deck buses.

Accompanying cuts show the character of stop signs which tell the public not only where the buses stop but also what routes go by a given stopping point.

#### Tying Street Railway and Bus Together

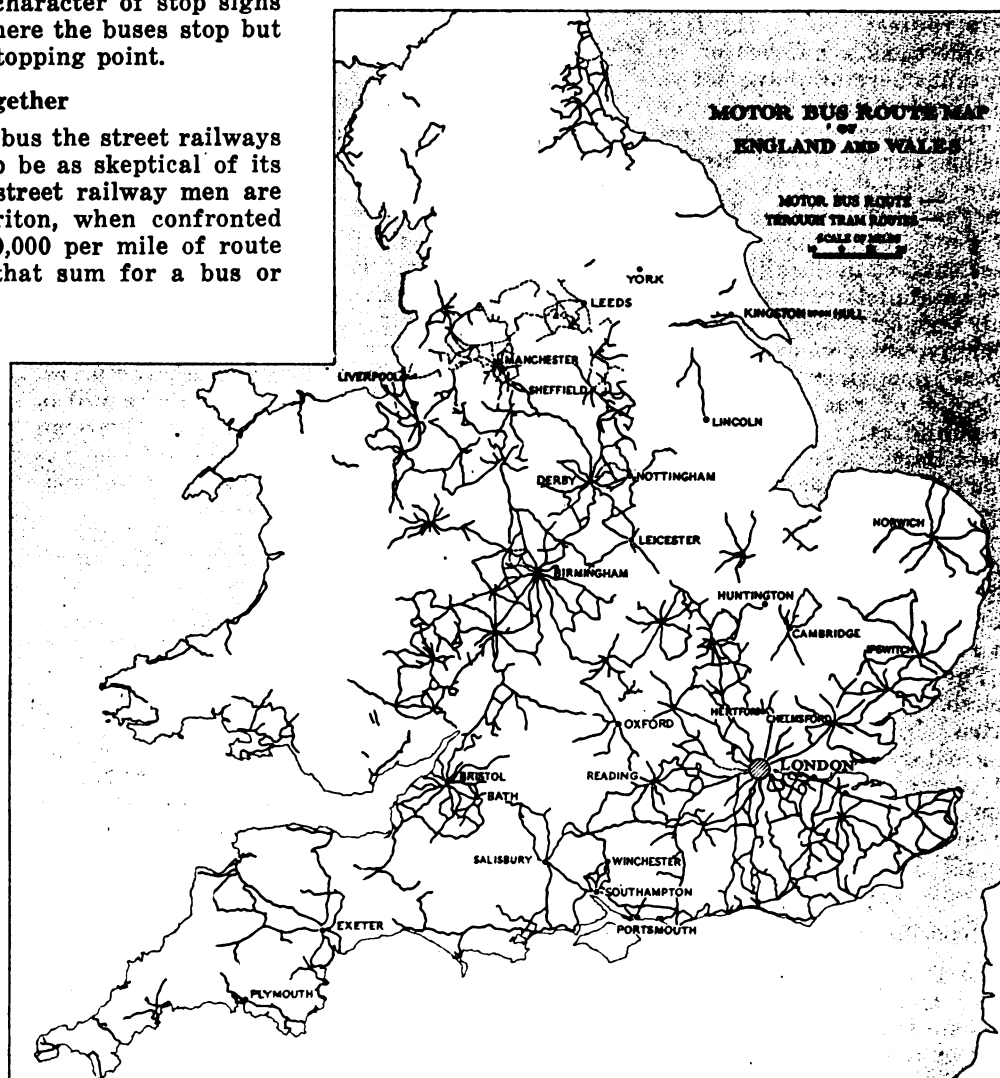

In the early days of the motor bus the street railways of Great Britain were inclined to be as skeptical of its possibilities as many American street railway men are to-day. But the hard-headed Briton, when confronted by the problem of spending \$100,000 per mile of route via the trackway, or one-tenth that sum for a bus or two to handle the traffic, did not hesitate long. Hence we find that almost all of the municipal tramways that are not running motor buses yet are petitioning Parliament for the right to do so. If it were not for the expense and time involved in getting these permits, the municipal railways of Great Britain would have much more extended bus services than at present. In some cases they have suffered the chagrin of seeing private companies put on motor bus services at will, even in competition with themselves, while they have been tied hand and foot by limitations placed on what the British call "municipal trading" and what we call "municipal ownership."

Of the installations studied on the latest trip made by the writer, Sheffield and Edinburgh were exceptionally interesting. Sheffield is the largest municipal combination of motor buses and trams; Edinburgh, with still more buses, bought within

two years, presents a novelty in that the present bus service is the successor to cable lines pending possible electrification.

The Sheffield installation, comprising 42 buses at the time of the writer's visit in June, 1921, is used primarily for extensions of the original trolley routes. This service has become so important that to-day the route mileage of the buses actually exceeds that of the street railways, the relative figures being 60 against 40. It will be understood, of course, that the greatest density of traffic is on the street railways, since these run through the densely built-up sections of the city. Thus it is that the buses carried approximately 5,500,000 passengers while the cars carried approximately 152,000,000 in the fiscal year ended March 25, 1920. It will interest the reader to learn that depreciation is on a seven-year basis, which corresponds, roughly, to 150,000 miles' life. As a matter of fact, the first buses were sold at public auction after seven to eight years' service.

Fares are higher on the bus routes to compensate for higher operating cost and thinner traffic. The rate per mile is  $1\frac{1}{4}$  pence, or slightly over 3 cents per mile, whereas the car fares are 1 penny (2 cents) per mile and 2 pence (4 cents) for the entire route. Bus passengers in Sheffield are usually transfer passengers—that is to say, they must use both car and bus in making the trip. Other British operators prefer to cater to the building up of direct through service. This is done by charging

Map reproduced from the T. B. R. (Travel by Road) guide showing the extent of the motor coach routes which form a network covering most of England, Scotland and Wales

Signs used in London to indicate the stopping points for buses which follow various routes

an excess rate wherever a street car is available, so that the city passenger is kept off of vehicles intended for the suburbanite.

A certain amount of Sheffield bus traffic also comes from people taking short rides to and from the steam suburban stations.

The relative fields of the motor bus and street car have been studied very carefully by A. R. Fearnley, general manager, Sheffield Corporation Tramways. In his paper before the 1919 convention of the Municipal Tramways' Association he showed that, despite the greater cost per seat of the bus, it was the most suitable vehicle for: (1) Connecting up cross-town routes; (2) relieving congested traffic by diverting part of it along other routes; (3) connecting up villages and rural districts.

The introduction of the motor bus as a part of Edinburgh's transport system came about through the taking over in 1919 of the antiquated cable system by the city of Edinburgh. Owing to the extremely high cost of new track and electric power facilities, R. Stuart Pilcher, general manager, recommended that certain of the northern routes be turned over to motor bus operation, pending the working out of electrification costs, etc. As the result of the experience gained with this service, especially in increase of traffic, the management has gained a clearer idea of the advantages and limitations of the motor bus. In his report of April 2, 1921, to the Council, Mr. Pilcher said:

"The limited accommodation of the bus is its chief disability. The bus cannot lift the crowds of people in emergency such as is done by a tramway car. On the other hand, it has the advantage of mobility and speed and of never being subject to the complete blockage of a route. It is rather strange that the bus, notwithstanding its restricted space and size, and sometimes congested condition, appears to receive a preference."

Further statements by Mr. Pilcher show that the introduction of motor buses lead to an increase in traffic as compared with the cable lines. Thus for the 11 weeks' period, January 8-March 19, 1920, the cars on one route

carried 990,314 passengers, but in the same period of 1921 the buses carried 1,102,761. This is not all, however, for the earnings per mile due to higher fares and greater density rose from 21.8 pence (43.6 cents) to 30.6 pence (61.2 cents), an increase of 17.6 cents per mile operated. In a general way it may be stated that the tendency of the bus has been to more than offset its higher running costs by its higher earning ability.

By the end of the fiscal year ended May 15, 1921, a total of 71 single-deck, 32-seat buses of A. E. C. and Leyland types were in service, carrying 10,158,810 passengers on eight regular routes, 1.5 to 6.5 miles long, and in various special services. The Edinburgh system also conducts char-a-banc service, few cities in the world having more attractions for the sightseer. Nine of the sightseeing cars seat 28 and six seat 32 passengers.

It must not be supposed that the rapid development of motor bus service in Edinburgh is due to exceptionally favorable conditions. On the contrary, there are many steep grades in this hilly city and the standard paving is of granite block. There are points—such as vibration—in which the service is open to improvement, as Mr. Pilcher has mentioned in his reports, but the flexibility and higher speed of bus service in Edinburgh have more than outweighed these difficulties.

In London the passenger has the option of underground railways and inclosed top-deck cars if the weather becomes too unpleasant. Such an alternative is not presented at Edinburgh. However, as the present standard capacity of 32 seats is rather low for two-men operation, the management is trying out a side-entrance bus which seats 42 passengers.

Edinburgh is the center of a great automotive service conducted to outlying points by the Scottish Motor Traction Company.

#### 126-Mile Overland Bus Service

Not satisfied with its triumphs in city and suburban work, the motor bus has been reaching out ever further afield to give either new or more frequent service to the country districts and to tie together places, 50, 100 or more miles apart. The largest of these undertakings is that of the Birmingham & Midland Motor Omnibus Company, Ltd., which operates more than 200 buses of the Tilling-Stevens gas-electric-drive type. There are also some double-deck buses in use. A significant fact is that this company is affiliated with the British Electric Traction Company, which was quick to recognize where motor bus operation is advantageous, and which now has a large number of installations, either in co-ordination with its tramways or entirely separate.

The Birmingham & Midland originally included a motor bus service in the city of Birmingham, but in 1914 the city of Birmingham took over the city buses and these are now a part of the local street railway and motor bus system. The number of routes exceed 100.

The variety of services given varies from the short-headway operation required in the suburban districts of a great city like Birmingham to the once-a-day run to a distant terminal. The most interesting example of the latter is that to Llandudno, Wales, a distance of 126 miles. This bus leaves Birmingham at 9.30 a. m. and, after making half a dozen intermediate stops, is in Llandudno by 6.10 p. m. Better running time than this is possible, but it has been found from experience that on long runs passengers appreciate the opportunity of stretching their legs. It is not desirable to tire patrons by making them sit in one place for four to five hours. A running speed of 30 miles an hour is entirely practicable on these trips.

The motor bus company does not pretend to compete with the railway in speed, but it gets a lot of business because so many people want to travel by road. However, the rates themselves compare favorably with the third-class charges on the railway. For example, the railway rate between Llandudno and Birmingham is 17 shillings 8.5 pence, while the bus fare is 16 shillings. So, too, the railway charges 16 shillings 2.5 pence third-class to Weston, 108 miles, whereas the bus rate is only 15 shillings. The business man may value his time highly, but there seem to be many more people who put comfort, cheapness and novelty ahead of time-saving; and that is why the long-haul bus prospers. Special rates are made for children, the concession usually being one-half the adult fare, except on holidays.

Passengers are permitted to take parcels up to 21 lb. in weight without extra charge; otherwise they are urged to ship heavier baggage via the company's combination of street railway and motor vans, said to be the only one of its kind in Great Britain and giving very largely a door-to-door service.

Unlike many motor coach operators, this company does not sell round-trip tickets. This matter of getting the return fare is left to booking agents at the terminals, who get a commission on sales. One reason for this policy is to avoid selling the same seat twice. In the case of the long runs it would be worth while to use the telephone or telegraph to avoid overlapping.

A pretty example of the ability of the motor bus to meet special situations is afforded by the policy of this company with regard to the Shakespeare summer festival held at Stratford-on-Avon. During this period the travel to and from Stratford is greatly increased, particularly by tourists and vacationists who want to enjoy the scenic beauties of Warwickshire, Worcestershire, etc., coming and going. To encourage this traffic the company is prepared to run special buses at ordinary round-trip fares between various outlying cities and Stratford for parties wishing to attend afternoon or evening performances. The only condition is that 25 passenger fares be guaranteed. Thus, people of the simplest means may enjoy the exclusiveness of the millionaire.

Ample care is given to publicity. Maps of the routes are sold for a penny and complete time-table with map for threepence, both through conductors. For sixpence the person interested in the beauty spots and famous places of the district can secure a handsomely illustrated booklet entitled "The King's Highway by Midland Red Motor Bus." The brilliant red coloring of these buses is in itself a good advertisement. A recent summer folder, entitled "Where Are You Going for Your Holiday This Year?" saved the reader the trouble of selection by showing the six best routes for a trip. As in the case of the motor coach companies, this operator's livery or private party service is a regular factor in the business—whether it be the conducting of parties to a play or to a football match. Circular tours are very popular, since those who partake in them get a maximum of sightseeing for a minimum of expense.

As the Birmingham & Midland offers such a good example of long-haul motor-bus possibilities, it will be unnecessary to describe other installations of like character. The company is deservedly proud of its record of safety and reliability in service. In 1920 it rolled up the total of 4,500,000 bus-miles. In May, 1921, it operated more than 40,000 miles per breakdown despite the long runs and many hills in its territory. This is a satisfactory answer to the question: Can motor buses be relied upon to give steady service day in and day out?

While the territory served by this company is excep-

tionally fine for pleasure travel, the writer found the motor bus no less popular in districts where nature and the highway departments have been less generous. This was particularly so in mining and mill districts where interest in sports is so keen that people will travel long distances to see their favorites play in the inter-county cricket or football matches. The hiring of individual motor buses by groups of friends makes these trips more attractive than rides on British railway cars with their isolated eight or ten-passenger compartments and their absence from the open road. The great increases in railroad fares and the excessive overcrowding of the trains in recent years, for one cause or another, have also been potent factors in drawing the masses to the overland motor bus.

### The Great Vogue of the Sightseeing Coach

Aside from the growing numbers and services of passenger motor buses, there has been an equally striking increase in the number of what we term sightseeing cars, and the British call motor coaches. The excellence of British roads, the Britisher's love of out-doors and the absence of American extremes in heat and cold all tend to the permanent popularity of this form of transport.

While our own sightseeing cars have been confined to turns about the large cities and nearby resorts, the British motor coach has reached out several hundred miles. The vehicles are of ever-improving comfort and luxury, with pneumatic tires to make the harder roads easy and suitable protection against changes in weather. The operators of these services are doing everything they can to promote the feeling that the ride on the coach to and from the vacation destination is a part of the vacation itself—not like a hot ride on a train. The fare is no greater than third-class railway. While the trip, naturally, takes longer than the train there is compensation in its agreeableness, and the sureness of a seat. These latter features are appreciated by many others than vacationists. It has been found that women, especially, will take all-day rides by motor coach in visiting distant friends—and this is true quite regardless of the season.

To stimulate traffic on off-days, the experienced operator also grants half rates on certain days or makes some other concession that will keep his investment busy. On some of the regular runs, there is a temptation for the passenger to return the same way by rail for the sake of saving time. This is offset by a liberal reduction in the round-trip rate. Thus where the one-way fare is 13 shillings, the round-trip fare will be 21 shillings instead of 26 shillings. Children in arms are usually carried free, and those under twelve years of age are carried at half rates except Saturdays, Sundays and other high-pressure times. The luggage of the patron is handled for him by the operator's own express vans under far more agreeable conditions than if he traveled by rail.

### Motor Coaching as a Business

Characteristic of the great development of the motor coach services is the work of the Samuelson Transport Company, which has taken all England, Scotland and Wales as its province. Its slogan of "First class service at third class (railway) fares" has been liberally advertised in newspapers, on billboards and elsewhere, so that the traveler is not left in much doubt as to the cost of a journey.

The term "booking for a journey" has a very real meaning in Great Britain, the Britisher being far more used to making reservations than we are. This practice naturally is a great help in the economical scheduling

of traffic, and is best for the traveler himself since he is assured of getting just what he expects. Seats for longer tours by day or week can be reserved by mail on forms. Either 25 per cent or all of the fare is paid on making reservation. In the former case, the remainder of the fare must be paid three days before the tour starts. For shorter runs, booking can be made with a shorter period of grace, either at the offices in London or at those of any booking agent throughout the country. In any case, all seats are booked in advance.

An important feature of this motor coach service is that the passenger's luggage up to 56 lb. is carried free in advance from the passenger's domicile to his next stopping place by special motor trucks or vans which call a day in advance. Excess luggage is handled at less than railway rates. Therefore, the vehicle is not encumbered with unsightly trunks or other baggage. The service also includes the reservation of hotel accommodation where that is desired.

A splendidly printed guide book describes the six to ten-day circular tours of North Wales, the Lake District, Devon-Cornwall and other beautiful spots of Great Britain. These are now made truly accessible by rubber-tire transport, for no vehicle on rails can approach the sight-worthy places so well or give the passenger so free and smokeless a view.

At the present time, this company is running daily services between London and the principal seaside and country resorts for passengers booked on regularly scheduled vehicles. The flexibility of motor coach service, however, permits the throwing in of many extra vehicles on any desired route almost instantaneously—as in concentration on the Derby or other great races. The Derby of 1921, by the way, was called the "Petrol Derby" because the coal strike left the handling of the vast masses who go to this race so largely to the gasoline vehicle. In addition to the regular touring and coaching services named, this company like others does a large business in carrying private parties to any part of the country via any combination of routes desired.

#### Road Sleeping Coaches Next

The hold which the motor coach has taken on the imagination of the public may be gaged from the fact that England's most widely-circulated newspaper, the *Daily Mail*, devotes several columns every Wednesday to this subject. The startling announcement has recently been made by one operator that he is preparing a night motor coach service between Manchester and London. Two night coaches with sleeping berths and other luxuries, he said, are already under construction.

#### The Legal Status of the Motor Bus and Coach

Although both motor buses and motor coaches pay a definite license to the Government, not all the questions that have come up through their widespread use have yet been answered. Operators of local transport undertakings—whether street car or bus—are rather afraid that these outside vehicles may pick up en route people who would otherwise take short rides with them. In one case, where the local transportation company complained it was shown that the only people picked up were those who had already booked their seats in advance. Nevertheless, the complainant held that these passengers should have been picked up only at the regularly designated booking station in town. If the latter practice were followed, patrons would be deprived of the convenience of having the vehicle stop at or near their homes. Generally speaking, the fear of such competition is exaggerated, inasmuch as these vehicles are not run for the rapid interchange of short-haul passengers.

28, DENMARK STREET, CHARING CROSS ROAD, W.C.2

Open 9 a.m. to 9 p.m. Sunday Included. Telephone: RECENT 915.

An example of one of the numerous posters used to advertise the extensive motor coach service operated by various concerns

The fewer stops they make, the better the service they can offer to the long-haul rider they are after.

The growth of overland or interurban motor coaching has also outstripped the facilities for loading and unloading these vehicles. In one large provincial city, the writer has seen forty to fifty coaches in the morning covering most of the chief public square and adjacent highways. Some towns allow the local bus and coach operators the use of their streets for parking while denying that privilege to the outsider, who is compelled to go to some garage or hotel. As the business grows, however, the cross-country operators are getting together to acquire definite parking spaces, the interests of these companies having been taken in hand especially by the Commercial Motor Users' Association and the Motor Trade Association. The first station opened in London this year is said to be that of the Brixton Motor Works, Ltd., which acquired a three-coach space that is available to anyone in the field.

Thus it will be seen that as in the case of the motor-bus, the Britisher has carried the sight-seeing car to a point far beyond our "Seeing Chinatown" and similar diffident, short-haul services. Indeed, he has made it an integral feature of the transportation facilities of the nation.

IT is stated on good authority that the present automobile production of Austria, which consists of Vienna and surrounding mountain districts, is greater than the entire German production. Naturally owing to the economic conditions in Austria, very few cars can be sold there, and practically the whole production has to be exported.

# Purpose, Aims and Possibilities of the S. A. E. Research Department

Manager of new activity gives his views of the functions to be performed and results sought. Difference between development work and fundamental research made clear. Society primarily interested in the latter.

By H. C. Dickinson\*

**I**N general the testing of any individual device or any particular material is not included in the definition of research. On the other hand, the study of methods of test as well as the deduction of general information from a systematic series of tests is properly so classed, although to be of value as research the results must be put in such form that they can be of general application.

Development research is recognized as clearly an exclusive function of the individual engineer and the industrial laboratory. By far the largest part of the work of all laboratories connected with the industry is of this nature and as such is recognized by the department as essentially confidential, whereas it is coming to be more and more generally recognized—although we regret, sometimes more as an abstraction than as a course of action—that there is much more to be gained than lost through a free interchange of all research information which is capable of general application.

The Research Department of the Society of Automotive Engineers will confine its efforts to explorational and intensive fundamental research. Much work of this nature, which is in progress in the industrial laboratories, will be of interest to the department and it is hoped that much more such work will be undertaken in the future. But with the major part of the work of these laboratories which is development work, we will not concern ourselves.

## Time and Effort Saving

An unbelievable amount of time and effort is wasted in the trial of expedients which a more careful application of the fundamental laws of physics and chemistry would have shown at a glance were based on incorrect assumptions. This fact was startlingly illustrated during the war when thousands of inventions of every conceivable sort were presented for consideration of the Government. It is safe to say that at least 90 per cent of these proposals showed such obvious and fatal errors in fundamental physical and chemical principles that they could be absolutely condemned at a glance. Of course most of them could be condemned equally on practical grounds, but one's judgment as to practical possibilities is by no means so safe a guide. Many things which look impractical do actually work, but so far as we know nothing works which violates the law of conservation of energy, or the second law of thermodynamics, or Newton's laws of motion, barring Einstein, or any other of a few hundred such principles.

Successful engineering research, as well as economical

development work, requires men with a peculiar combination of broad fundamental knowledge and sound common sense, with the enthusiasm of the typical inventor but without his typical shortcomings.

The most common incentive for the organization and continued support of research laboratories or of any systematic research program is necessarily the commercial one. In fact, this is almost the only one if we except some of the educational laboratories which have been endowed purely for the sake of the advancement of science. Thus almost every research laboratory and particularly the industrial ones present a constant conflict between these two points of view which are somewhat incompatible. The true research worker is interested in securing facts and will not be satisfied until his results are complete. Moreover, every problem he undertakes presents to him numerous side-lines which are of absorbing interest. If given his own way, unless he is endowed with unusual self-control, he will either carry through his problem to a final conclusion or switch to some side-line of greater interest, according to his temperament. On the other hand, the director of the laboratory or the "man who pays the bills," unless endowed with unusual patience and foresight, will, as soon as some fact of apparent commercial value is developed, recommend dropping the research and developing something useful. A happy compromise between the two points of view is difficult to attain. But a real compromise is necessary since both viewpoints are important and neither side may be neglected.

Up to within the past few years the United States, which has shown by far the greatest industrial development in our line, has contributed comparatively little to the sum of automotive research. The work of British and German experimenters had to serve the needs of our own engineers even though it was entirely inadequate for our needs. In the past few years, however, there has been a general awakening to the need of research among members of the Society. Its importance has been so ably presented in recent papers and discussions that it is hardly necessary to further emphasize this phase of the subject. We are now awake to the need, and once awakened the United States will not lag behind. In fact, perhaps a warning is needed that while the possibilities of research can hardly be overestimated, the realization of these possibilities in terms of industrial results, rests with the engineers in charge of design and development. No matter how many and able the research engineers, nor how important their conclusions, these conclusions will be of value only insofar as they are embodied in successful design.

In general, the object of the Research Department is to secure through concerted effort more, and more re-

\*Abstracted from a paper by the author, recently appointed Director of the Research Department of the Society of Automotive Engineers, read at a recent meeting of the Detroit Section of the Society.

liable, fundamental technical information for the use of the members of the Society and to make this information more easily available. The distribution of information may be handled in several ways.

Fundamental research is in the last analysis almost entirely a question of men rather than of equipment. Many of the most important scientific results have been obtained without laboratory equipment worthy of the name. A study of the research situation in the various laboratories leads to the conclusion that these laboratories are even now sadly undermanned, particularly with men of real ability. To establish a new laboratory could not increase the supply of first-grade research men; hence it would have to be manned at the expense of existing institutions. Thus, whatever results the new laboratory might attain would be at the expense of other institutions and the net result would probably not be increased research. It appears therefore that the department can most profitably devote its efforts to assisting existing laboratories.

The three classes of laboratories—educational, industrial and independent—occupy altogether different positions in regard to research, and any general plan must take account of these differences. It is recognized that the prime object of the industrial laboratories, those directly connected with the various manufacturing companies, must always be development research. But in connection with this we hope there will be accomplished an ever-increasing amount of fundamental research work which can be made of general value—such work as deals with general principles rather than specific questions of design. It is a very common experience to find one laboratory undertaking a research intended to cover some problem which has been carefully covered elsewhere, but no record of which is available. It is one of the aims of the Research Department to secure, so far as possible, the publication, or at least a record of such non-confidential general results and to act as a clearing house of information on research problems of this character. For the most part, the various laboratories are rather well supplied with problems, but from some institutions where new facilities or new men have become available, there have come requests for suggestions as to problems or general lines of work which might be taken up to advantage. It would seem that here is a splendid opportunity for better use of the educational laboratories by the industry. The custom of farming out individual research problems has been followed to some extent, but there is room for much more of it. The Research Department stands ready to offer any possible assistance in securing more co-operation of this kind.

#### Duplication of Research

Recently very much caustic criticism has been heard regarding duplication in all sorts of connections, including research. One might make remarks about the duplication in criticism. Research is always a matter of duplication since no physical fact is ever established except through repeated observation. Much apparent duplication is not only desirable but necessary. Nevertheless, this applies to intelligent duplication only. Not much is to be gained by having several different laboratories working on the same problem unless each knows something about what the other is doing. This latter sort of duplication should be avoided particularly among the educational laboratories so far as possible. Since the results of most research are not to be had in print for months or perhaps years after the work is begun, the most promising means of preventing unnecessary repetition seems to be through some central clearing-house

for work proposed and in progress. This function the Research Department will hope to fulfill.

One of the important objects of the Research Department is to assist toward the development of a more systematic program of research throughout the industry. The formulation of such a program is too much of a problem to be solved for some time to come. It must be built up little by little with the co-operation of the members of the Society.

#### General Research Program

There are, however, two broad general problems which are brought to our attention at once by their importance and the insistent demand for immediate information. These are the fuel problem and the highway problem.

A very important question is, What is the relation between endpoint or volatility of fuel and the average fuel consumption in actual service? To answer this we must know what constitutes upper limit of volatility—is it endpoint or something else? Mr. Wilson of Massachusetts Institute of Technology has brought out something of interest here, but the question is not yet answered.

The highway problem has received less attention by the automotive industry partly because its importance seems to have been less recently appreciated and partly because it does not appear at first sight so immediate a problem of the industry. It has been heretofore mainly a question of "good roads." So far as the passenger car alone is concerned, this may be largely true. Considering, however, the broad question of the economics of highway transportation, the problem is distinctly an automotive one. It is not possible to consider only the design of a truck, for instance, that will give maximum ton-miles per dollar if it has a road to travel on, without including also the cost of the highway. So long as registration fees for passenger cars paid for good roads, we were all reasonably content, but as soon as the highway is commercialized, so to speak, someone will be inquiring about the proper distribution of the highway bill among the different classes of traffic. Some answer to this question will have to be made. Perhaps it is a problem for the road engineer, but the automotive engineer will be very much interested in both the answer and the method of arriving at it. The nature of this answer or the relative license fees which may be based on it will be a large factor in deciding what sort of truck will be most economical for any given class of service.

THE quarterly progress report of the British Electrical and Allied Industries Research Association (E. R. A.), states that the council is carrying out a comprehensive program of research at the National Physical Laboratory. Tests are being made upon cotton fabrics dressed and undressed of various weights and treated with varying thicknesses of varnish. A collection is being made of samples of treated fibrous insulating materials with a view to classification before proceeding with tests. A complete series of purchasing tests is to be made on samples of untreated papers used for various electrical purposes, the investigation including the testing for impurities such as metallic inclusions and carbon obtained from soot in the atmosphere, as well as porosity conditions. A large number of samples of treated papers has been collected. The numerous other materials in use have been classified, with the exception of vulcanized fibers, and a preliminary schedule of acceptance tests for purchasing purposes has been prepared.

## Service—An Aid or Hindrance to Sales?

**A**NALYSIS of the market for future car sales indicates definitely that service will play an increasingly important part in selling. It will be a sales resistant or a sales help, depending largely upon the way in which service is handled during the next few years. The percentage of replacement sales is constantly mounting, and in every such sale previous service experiences will be a factor in buying. The man who has never owned a car may not consider service facilities and methods very seriously, but the man who is buying his second or third car will be influenced definitely by his past experiences as regards buying parts and having repairs made.

This fact should be fully recognized in discussing service policies. The manufacturer of cars and trucks is in business to make a profit from the vehicles which he sells. He will ultimately make the greatest profit if his product is serviced to the satisfaction of the user. The user will be best satisfied when he re-

ceives the best possible service at least possible cost.

A prominent student of this question recently defined service as "taking care of the owner; making the owner satisfied." Service of this kind will mean lessened sales resistance and consequently greater profits. From a purely business standpoint this should be the basis of service policy discussions. The question as to who should have the right to sell parts must ultimately be solved by allowing the person to sell the parts who can do it the most economically. Efforts along this line will be of more permanent value than any attempt temporarily to resist economic laws.

## Improving the Fuel as Well as the Engine

**T**HERE is a disposition among automotive engineers as a class to accept as inevitable the general tendency toward a decrease in the volatility of motor fuel without much thought being given to the benefits which would result if the fuel as well as the engine could be improved instead of being allowed to deteriorate in quality. There are, fortunately, some few engineers who insist that it is neither just nor expedient for the automotive industry to bear the burden of continually changing engines to meet, or attempt to meet, the conditions imposed by having to utilize poorer and poorer fuel, while the petroleum industry sits back and serenely assumes that it is impractical to improve the quality of fuel—that the only way to meet the demand for motor fuel is to continue to cut deeper and deeper into the crude with corresponding decrease in volatility.

It is at least conceivable that the entire petroleum motor fuel supply might in some way be so changed as to render it usable in much higher compression and consequently more efficient engines, and that by this means the tendency toward increasing total consumption might be checked and the available supply made to go much further, while at the same time engine performance is improved. This apparent possibility is the subject of intensive research on the part of one of the largest automotive manufacturers in the country, and there are indications that at least one of the large petroleum refiners is giving the matter serious attention.

This is said to have been brought about by the fact that one of the large oil companies retailing gasoline in and about Baltimore recently experienced a marked falling off in the sale of this fuel because of the competition resulting from the marketing of benzol-gasoline blends. The latter performed so much better than straight run gasoline that the public readily paid a slightly higher price for it and greatly decreased purchases of straight gasoline resulted. The oil company was thus forced to market a benzol-gasoline blend of its own.

The limited supply of benzol available makes it impossible to follow this practice generally over even a large proportion of the country, but it has at least shown the oil companies that there is a sufficient difference between certain fuels for the public to be

willing to pay more for the better grade, even though it cannot realize the full benefits which would result if the compression of the engines it is using could conveniently be raised.

It is to be hoped that the lesson taught by this situation will not be lost. There is good reason to believe that crude oil contains, in one form or another, hydrocarbons which, when blended with gasoline, give the fuel desirable characteristics similar to those which benzol-gasoline blends possess. In any case this and other possible means for improving fuel should be made the subject of intensive research and automotive manufacturers should allow no opportunity to pass to impress this fact upon the fuel industry as well as upon Government agencies in a position to co-operate to the same end.

## Interchangeability in Toothed Gearing

PRACTICALLY all systems of cutting gear teeth developed in the past were conceived in the belief that a practical gearing system should be interchangeable so far as numbers of teeth are concerned. For instance, in the standard involute system the smallest number of teeth is twelve, and a pinion with this or any other number of teeth will run satisfactorily with a gear of any number of teeth, up to a rack. This interchangeability, of course, is a valuable feature from the standpoint of the gear jobber who carries gears in stock and receives calls for all possible combinations. But it is of absolutely no advantage from the manufacturing standpoint. For instance, in the case of a train of gears in a machine, if one of the gears breaks or wears out, it must be replaced by another with the same number of teeth, because the center distance is fixed. In rear axle bevel gear drives it is sometimes desirable to offer an option on different reduction ratios, but any bevel pinion will mesh properly only with a bevel gear of a certain number of teeth, and the above remarks apply to spur gears only. The great majority of gears that are cut to-day are intended for a definite purpose, and what kind of mating gear they have to run with is definitely known before they are made. The interchangeable feature is then no advantage at all, and the sacrifices made to attain interchangeability are futile.

That a sacrifice in efficiency is necessary to gain this interchangeability is well known. The case is similar to that of combination tools. You can make a tool that will serve as a hammer, screw driver, wrench and several other things, but if you are using a hammer continuously you do not want that kind of tool; a tool designed for one purpose only will do the work better. Similarly a gear specially designed to run with another gear of a definite number of teeth can be made more efficient than one which has to be given such a form that it will run properly with a gear with any number of teeth from twelve to infinity.

In spur gears the tooth action is partly sliding and partly rolling, and the frictional losses naturally de-

pend very much upon the proportion of these two forms of motion. It is within the power of the gear designer to vary this proportion within certain limits. This ratio depends upon the pressure angle, the relative number of teeth in pinion and gear, and upon the addenda and dedenda. When interchangeability with respect to tooth number is not required, the designer is more at liberty to vary these factors so as to obtain a greater proportion of rolling motion, and hence a higher efficiency.

That manufacturers are paying too high for interchangeability, or, rather, are paying for something that is of no value to them, is gradually coming to be recognized, and a move seems to be shaping to break away from it. The system has been standard practice for so long that many have come to regard it as the last word in gear practice, but in this day of keen competition any standard that has outlived its usefulness is given short shrift, and it would not be surprising to see the interchangeable system of gear cutting discarded in manufacturing before very long.

## Foreign Selling Practices

THE success of certain foreign countries in international trade has been largely the result of uniform practice among manufacturers in conducting their foreign business. The German *cartels* were largely instrumental in aiding that country to gain and hold so many foreign markets.

This lack of knowledge among American manufacturers of what other manufacturers are doing has operated also to the detriment of each individual. The individual automobile exporter has not had the advantage of knowing in any accurate manner how his practices correspond with those of other manufacturers. Each exporter has had to blaze his own way to a certain extent.

In an effort to render practical service to the automobile industry, the recently reorganized Bureau of Foreign and Domestic Commerce is about to send to the various manufacturers a questionnaire designed to find out facts concerning various practices in connection with our foreign selling. While this questionnaire will deal with rather intimate information, the results will be held entirely confidential, as are income tax reports. The data obtained will be compiled in percentage form and the results made available to all the manufacturers in the industry.

Manufacturers will be enabled to know what is common practice; the Bureau will be able to examine foreign selling conditions in the light of these results and to give the manufacturers accurate and practical information that will be of real value in future foreign selling efforts.

The new Automotive Section of the Bureau of Foreign and Domestic Commerce is making a sincere effort to find out what practical information the industry needs and to secure that information in the most rapid and efficient manner possible. The success of this effort will depend largely upon the degree of co-operation extended by manufacturers both in supplying information and in giving constructive suggestions.

## Parts Makers Report Better Dealer Trade

### Increased Commitments Made to Meet Needs Developing in Near Future

NEW YORK, Oct. 26—Parts and accessory manufacturers who deal with automobile distributors and dealers are virtually a unit in reporting increased sales to this branch of the trade. They say there has been a marked improvement in the tone of this market and that the men who deal in automobiles rapidly are regaining their confidence. They have ceased to buy entirely on a hand-to-mouth basis and to an increasing extent are making commitments to meet needs likely to develop in the near future.

Business of the parts makers with manufacturers for October will show a slight decline from the volume of September in a majority of cases, although there are many concerns which report that their production has not been decreased and some which have had better sales. Generally speaking, conditions in the parts field are somewhat better in the east than in the middle west, except in the Milwaukee territory.

### Collections Satisfactory

Collections on current business are entirely satisfactory. In this respect there has been a steady improvement in conditions each month since the beginning of the year with one exception. The chief concern of the parts maker is over the old orders which have been on his books for many months and for which materials were purchased before his customers ordered him to hold up shipments.

Stronger efforts are being made to liquidate the cash tied up in materials of this character. Some progress has been made each month but it has been a dreary job. The parts men have been reluctant to take their troubles to the courts and seek to enforce legitimate contracts. As a consequence about the only way they have been able to move fabricated and partly fabricated stocks waiting for release has been to make price concessions. This usually brings results from customers who have ready cash.

### Expect Tapering Off

Parts makers generally expect a gradual tapering off of business from now until the close of the New York and Chicago shows. Most of those in the middle west are basing calculations on a greater decline than are those in the east. They are a unit, however, in the belief that fundamental conditions are growing stronger day by day and that there will be a steady improvement in conditions after the first of the year. They do not expect a boom and want none. Their expectation is that each month will show a gradual improvement over the one preceding, although they

look for greater seasonal declines than have been apparent this year.

While there is no concern in the parts field over the trend of business, there is apprehension lest some of the smaller automobile companies may fail to weather the storm. This relates to companies which have done little or no business for more than a year. There are more truck than passenger car concerns in this category.

There is a considerable number of companies, almost without exception comparatively small, which are virtually in the hands of their creditors. Every effort will be made to save them, but some have reached the limit of their resources.

The situation in regard to finances is exceedingly gratifying on the whole, however. There have been no really large failures and there is no fear that there will be. Few companies have all the cash they need, but this condition is occasioning no alarm, although the burden of carrying creditors is bearing down more and more heavily on the shoulders of parts makers.

## Three More Distributors Are Taken Over by Willys

BOSTON, Oct. 24—At a dinner of the dealers comprising the Eastern New England territory numbering 160, President John N. Willys, of the Willys Overland Co., announced the taking over of the distributor organizations at Boston, Portland and New London. The largest of the three is the Connell & McKone Co., of Boston. Willys stated that the discount to the distributor had to be reduced in order to increase that to the dealer.

The Connell & McKone Co. will continue selling Overlands at retail at its Worcester, Quincy and Manchester, N. H., branches. The Wentworth-Smith Corp. of Maine, taken over, will sell the line at Portland and Augusta.

The personnel of the new factory branch at Boston will be W. G. Northrup, formerly manager at Springfield, Mass., New England branch manager; Weldon McKone, Metropolitan Boston manager; C. R. Arenschield, wholesale manager; C. F. Boles, service manager.

## Jackson Is Taken Over by Associated Industries

JACKSON, MICH., Oct. 27—Announcement was made here to-day that the Jackson Motors Corp. will be taken over on Oct. 29 by the Associated Motors Industries which was incorporated recently in Delaware with a capital of \$80,000,000. The real property of the Jackson corporation will be purchased for \$1,105,000 in the preferred stock of the new company. Merchandise claims and bank indebtedness will be paid in bonds and stock following an appraisal.

The Associated Motors Industries proposes to take over at least a dozen other companies with physical assets valued at more than \$50,000,000.

## Supreme Court Ends Perlman Rim Action

### Refuses to Review Decision of Lower Courts in Long Standing Litigation

WASHINGTON, Oct. 24—Refusal of the Supreme Court of the United States to review the decision of the lower courts brings to an end the litigation concerning the right to manufacture demountable automobile rims. The appeal of the Perlman Rim Corp. against the findings of the courts below in favor of Louis deF. Munger deals with the infringement of patent rights. The petitioner presented the question of validity and scope of the alleged invention of Munger. However, the action of the court allows the judgment of the lower tribunals to stand.

The Perlman corporation insisted that their appeal was in the public interest inasmuch as approximately one-half of the 9,000,000 of the automobiles in service are equipped with a set of five demountable rims and the decision of the courts below authorizes the collection of royalties by Munger amounting to \$.1399 per rim. It was claimed that the effect of the decision below is to give Munger a monopoly in respect to wedging a tire to a rim.

The court was advised by the Perlman corporation that "Munger's principal invention was a non-collapsible tire and not a demountable rim." They furthermore claimed that the secret of the Perlman invention was the conical fit with the free space between the surfaces, except the narrow line of contact. This suit was instituted about five years ago.

## M. A. M. A. Plans Mature for Export Department

NEW YORK, Oct. 21—Plans for the promotion of an export department within the Motor and Accessory Manufacturers' Association are being matured. A strong committee will be appointed to initiate the work and carry it on. It is proposed to co-operate closely with the automotive division of the Bureau of Foreign Commerce. The M. A. M. A. headquarters in New York will be used as a clearing house for all export information in relation to possible markets for accessories and parts.

### HUFFMAN ACTIONS DISMISSED

ELKHART, IND., Oct. 24—The Circuit Court of Elkhart County has dismissed actions filed against Huffman Brothers Motor Co. by creditors with claims aggregating \$14,845. It is understood the claims have been paid. They were filed by the Goshen Buggy Top Co., the Ligonier Automobile Body Co., the Marion Malleable Iron Works and the Woonsocket Mfg. Co.

## Goethals to Handle New York Operations

### Plans Are Developed by Port Authority in Case Strike Develops

NEW YORK, Oct. 24—Governor Miller has vested in the Port of New York Authority, a board established by the states of New York and New Jersey, authority to handle all transportation facilities available in the event of a railroad strike. A plan of operation to meet an emergency already has been worked out by Elihu C. Church, consulting engineer to the Port Authority. General George W. Goethals has been selected commander-in-chief of the motor service.

The essentials with which the city must be supplied in the event of an emergency are food, including staples, milk and forage for horses; mail; gasoline and coal. There also will be some essential long distance passenger transportation and some essential commuter business.

The means of transportation in the event of a strike will include a few railroad trains, depending on the number of locomotive engineers available, trucks, barges and ships.

#### To Police Road Traffic

In the event of a strike one member of the Port of New York Authority will be in touch with the retailers to determine what supplies are needed and where they are most urgently required. Another will keep in touch with wholesalers in the Metropolitan area to determine where such supplies can be found.

Another member, working with the state highway commission, will have authority to declare certain roads trunk lines and to close them to other traffic for a certain period during which another member of the board will arrange to have freight collected at a central loading point and still another member will allocate transportation units to that particular haul. Trucks using the trunk lines will move in convoys both ways under direction of motorcycle patrolmen.

Other members of the board will see that the necessary number of vehicles are available, that trunk road traffic is policed and regulated, that trucks are dispatched on time, that there are facilities for repairs in case of breakdown, that proper loading and unloading facilities are available and that each unit of transportation hauls a full load.

The Port of New York Authority also has collected all the data available on the number of trucks available in the Metropolitan area.

#### Parts Makers Will Use Trucks

NEW YORK, Oct. 24—Information received at headquarters here of the Motor and Accessory Mfrs. Assn. indicates that a great majority of the members are determined to continue factory operations by the use of motor trucks if there is a railroad strike. A majority of them

have well balanced inventories and would experience little difficulty in keeping production at present levels unless the railroad strike lasted several weeks, which is considered highly improbable.

Arrangements will be made by parts manufacturers to make deliveries regularly by motor truck. It is believed that if there is a general strike many shippers who will be forced to resort to the use of trucks never will go back to the railroads for short hauls because of the advantages which they will find in motor transport.

#### Club Offers Services

TRENTON, N. J., Oct. 21—The Motor Truck Club of New Jersey has offered its services to Governor Edwards in the event of a railroad strike. The trucks controlled by members of the organization would be used first for moving food-stuffs and fuel.

#### Measures Taken in Chicago

CHICAGO, Oct. 24—Defensive measures in case of a general railroad strike have been undertaken by Chicago. The Association of Commerce will look after the food supply, fuel, etc. The city has on hand food to last three months, and the coal in storage, excluding industries, would last for a year. The milk supply of the city is less than 100 miles and will be handled by trucks.

#### Kentucky Prepared

LOUISVILLE, Oct. 24—Should the railroad strike be called as threatened, Kentucky has 14,122 motor trucks to combat the cessation of train service, figures obtained from the State Department of Automobiles, show.

## Ford Says Manipulators Are Behind Strike Move

NEW YORK, Oct. 25—The threatened railroad strike is only "an attempt on the part of the manipulators" to bring about deflation, is the opinion of Henry Ford, and no one but the manipulators could possibly gain anything.

"The workmen have nothing to gain," Ford said in an interview at his New York headquarters. "I have talked with many of them during the past week and none knew definitely what he proposed to strike for. The public likewise has nothing to gain and much to lose if the strike actually goes into effect. The gang wants to get prices down so they can get in on more of the profits."

"We have no labor problems on the Detroit, Toledo & Ironton Railroad. All the workmen are paid on the same basis as the men in the Detroit factory. This is a higher rate than that paid to labor on other railroads. The 450 miles of road is now being operated profitably in spite of the fact that the workers are better paid than previously and even so we have reduced freight rates in whatever instances the Interstate Commerce Commission permitted."

Reverting to the automotive industry, Ford declared with emphasis:

"The world is on wheels. I have no fear for the automobile business. Why should I? Our branch across the river in the meadows on ground that used to be a swamp, now does a business of \$60,000,000 a year."

## Indiana Industries Join to Meet Strike

### Questionnaire Is Sent Out in Order to Obtain Truck Details

INDIANAPOLIS, Oct. 24—A definite detailed plan to meet the emergency of a railroad strike by means of highway transport has been presented to Governor McGray by Tom Snyder, secretary of the Indiana Highway Transport and Terminal Association, and Lynn M. Shaw, secretary of the Indiana Automotive Trade Assn. Under the plan 19 statewide industries in the transport, transfer, warehouse and automotive fields will co-operate. The plan provides for the appointment of a transport commissioner and a highway supervisor to direct traffic over the most suitable highways. The entire state would be zoned and the various units co-ordinated.

It is expected that approximately 50 per cent of the 40,000 trucks of the state will be available for use in the event of a strike. Every important center in the state has been reached by a questionnaire sent out several days ago and reports are being received by every mail giving the number of trucks each concern reached can devote to the emergency.

#### Fix Rates

Exact details of every truck pledged are being tabulated, giving the size, the kind of bodies used, the rates at which they will operate and the routes, warehouses and terminals to and from which these vehicles can operate most efficiently. In almost every case the rates to be charged for motor freight and express down to third class will be the common carrier rates, although some of the units will have to be assured of return loads to make this figure possible.

The Indiana Highway Transport and Terminal Association and the Indiana Transfer and Warehousemen's Association will form important units around which the emergency system will be built. There now are nine motor express lines radiating from Indianapolis with terminals in Crawfordsville, LaFayette, Marion, Kokomo, Muncie, Greengburg, Columbus and Bloomington.

The Indiana Federation of Farmers and the Indiana Automotive Trade Association will co-operate.

In Indianapolis alone, there are 2338 trucks engaged in the distribution, transfer, cartage and transfer service.

#### DUSENBERG WANTS MEDAL

PARIS, Oct. 16—Through the representative of the American Automobile Association, the Duesenberg company has put in a claim for delivery of the gold medal which constitutes the "Grand Prix" of the Automobile Club of France. The medal was won by Murphy in the race at Le Mans last July, but was not ready for presentation when the team sailed for America.

## Ford English Sales Reported Improved

### Output of Foreign Plants for September Aggregates 4525 Cars and Trucks

DETROIT, Oct. 26—Total production in the Ford Motor Co. plants outside the United States and Canada was 4525 cars and trucks in September. These were built in Buenos Aires, Copenhagen, Bordeaux, Sao Paulo, Cadiz and Manchester. The Manchester plant output was 2631. Ford Motor Co. of Canada produced 2937.

Sales in England are reported better than they have been for some time with business conditions showing a much firmer tone. Post-war depression is reported giving way not only in England but in many parts of the Continent and much better foreign trade conditions are looked for.

All Ford branches throughout the United States continue operating on a large scale. Detroit led in September assembly with 7408. Kearny, N. J., was second with 7036, Chicago third with 6000 and St. Louis fourth with 5525.

Body production at the River Rouge plant, Detroit, is on the increase, particularly in touring car bodies. Fordson tractors to the number of 827 were built in September at the Rouge plant.

Reports that a large part of the River Rouge plant would be set aside for the manufacture of gasoline propelled railway equipment, from hand-cars to locomotives, are denied at the plant. Equipment of Ford's railroad is overhauled in a section of the Rouge, but manufacturing is not under consideration.

## Portage Stockholders Make Counter Offer

CLEVELAND, Oct. 24—Stockholders of Portage Rubber Co., which F. A. Seiberling offered to buy for \$750,000 have made a counter offer of \$1,000,000 to the referee in bankruptcy. The referee recently ordered the Seiberling offer accepted by the trustees, unless stockholders demurred or offered a counter proposition before Oct. 21. Immediate hearing of the stockholders' proposal is expected, although final decision rests with Federal Judge Westenhaver.

## New Maccar Truck Model, 2-Tons, Listed at \$3,300

SCRANTON, PA., Oct. 25—An additional model, of 2-ton capacity, and known as Model H-A, has been developed by the Maccar Truck Co.

It is fitted with a Continental four-cylinder  $4\frac{1}{2} \times 5\frac{1}{4}$ -in. engine, Maccar fin and tube radiator, Zenith carbureter, Eisemann high-tension magneto, Mueller governor, Brown-Lipe gearset and clutch, Spicer universals, Merrill

springs, Ross steering gear and Timken worm-drive rear axle. The truck has a wheelbase of 150 in. and is also made in a long model with 162 in. wheelbase. The rear axle is of the full floating type and gives a reduction of 8.5:1 on high and 45.47 on low gear. The frame is made of alloy steel  $\frac{1}{4}$ -in. stock, the channels having a height of  $6\frac{3}{16}$  in. and a width of  $2\frac{1}{2}$  in.

Of the total weight of the loaded truck 70 per cent rests on the rear axle and 30 per cent on the front axle. The weight of the complete chassis is 5200 lbs. Steel wheels are fitted, with solid tires  $36 \times 4$  in., single in front and the same size dual in the rear.

The chassis price is \$3300.

## G. M. C. Stockholders Show 1513 Increase

NEW YORK, Oct. 24—The number of shareholders upon the books of the General Motors Corp. Oct. 3 was the largest in its history. The record taken in connection with the quarterly dividends which will be paid upon Nov. 1, showed 66,837 names, an increase of 1513 over the preceding quarter, and an increase of 29,943 over a year ago. The detail of the number of stockholders receiving dividend checks upon Nov. 1, compared with the preceding quarter follows:

Classes of Stock	Nov., 1921	Aug., 1921
6% Preferred.....	\$3,208	\$3,170
6% Debenture.....	10,083	10,107
7% Debenture.....	8,906	9,046
Common .....	44,640	43,001
Total .....	\$66,837	\$65,324

## Industry Contemplates Safety First Campaign

NEW YORK, Oct. 24—A movement is under way for the organizations within the automotive field to co-operate in the promotion of a vigorous safety first campaign to cut down highway accidents. It is realized that the large number of fatalities and injuries caused by motor vehicles has become a sales deterrent, and it is believed the industry should play a larger part than heretofore in combating carelessness not only of pedestrians but of drivers.

If such a campaign is undertaken all manufacturers and dealers will be asked to co-operate not only in their own communities, but in a nationwide educational effort to promote the use of safety appliances. Many accidents are due to faulty brakes, for example, and it is believed a campaign to bring about more careful and frequent inspections of brakes would do much to prevent accidents.

### HINKLEY TRUSTEE APPOINTED

DETROIT, Oct. 24—The Security Trust Co. was named as trustee for the Hinkley Motors Corp. at a meeting of creditors before a referee in bankruptcy. An involuntary petition against the company was filed recently by three minor creditors.

## Makers and Dealers Arrive at Agreement

### N. A. C. C. Committee Will Submit Conference Proposals to Members for Final Action

DETROIT, Oct. 24—Committees of the N. A. C. C. and the N. A. D. A. have closed the series of conferences which have been held on contractual relations by arriving at tentative agreements on the points outlined. These will now be submitted to the membership of the N. A. C. C. for consideration and final action.

In a statement following the meeting, Alfred Reeves, general manager of the N. A. C. C., said his organization was in complete harmony with the dealer group and was deeply interested in helping overcome the obstacles now interfering with the safe progress of the industry. Every effort will be made, he said, to clear away the difficulties with which the trade is now faced so that there will be no unnatural barriers to sales in 1922.

### To Stimulate Sales

One of the important actions taken at the conference in a sales stimulating sense was the decision to make the New York and Chicago national shows more merchandising events than they have been in the past. Recommendations will be made to the show committee of the N. A. C. C. which are designed to give dealers greater opportunity to develop sales on the show floor than at former shows.

A decision to go to the mat with the used car situation immediately was another matter upon which an agreement was reached and recommendations will be made to manufacturers at once so that dealers may have united backing in the movement. It was agreed that trade-ins are a necessary factor in doing business but that they can be handled in such a way that present abuses may be avoided. Reeves said a survey of the used car situation is now being made which upon completion will permit the manufacturers to approach the subject with a more complete knowledge of its ramifications.

### Discountance Truck Trades

The process of cure will be slow, he said, in view of the extensiveness of the evil, but it will be brought under control. The committees were agreed that trade-ins in trucks should be discountanced. N. A. C. C. representatives attending the conference were: W. E. Metzger, chairman; Colin Campbell, Hal B. Boulden, F. E. Conner, W. E. Voorhis, Percy Owen and Alfred Reeves. For the N. A. D. A. they were: Jesse E. Smith, Harry Harper, N. H. Cartinhour, Fred W. Vesper, J. E. Eldridge, Harry G. Mooock.

Directors of the N. A. D. A. who had attended a meeting preceding the joint conference were invited to sit in at the session.

## Little Change Seen in Retail Car Trade

### Outlook for Enclosed Models Especially Bright—Truck Sales Increase Steadily

NEW YORK, Oct. 25—The trend of retail trade in passenger cars has shown little deviation in the past week from the level of the last six months. The first half of October was surprisingly good, but a gradual slowing up of sales is to be expected in most sections of the country as the touring season closes. The outlook for enclosed car business is uncommonly good, however, and nothing has arisen to change the belief that the aggregate of sales in dollars for October will equal September.

There is evidence of a growing opinion among body makers that there is too great a difference between the prices charged by car manufacturers for open and enclosed models. It is held in some quarters that not all this margin is justified, and some body builders are inclined to stand pat on their prices for enclosed jobs until the cost to the ultimate consumer is reduced.

### Strike Will Help Trucks

Truck sales are increasing slowly but steadily as general business conditions improve. A fillip has been given them by the threat of a general railroad strike. The strike menace has given tremendous emphasis to the essentiality of motor vehicles as transportation units. Their reliability is proven by the fact that the nation has turned instinctively to them in the face of an emergency, in the realization that their mobilization will prevent industrial paralysis if the carriers cease to function. Manufacturers and dealers are taking advantage of the opportunity to convert bankers who have been skeptical about handling truck paper.

If there is a railroad strike it will not have a demoralizing effect on automobile production unless it is longer lived than is probable. Most passenger car makers have inventories sufficiently large to permit production for some time without bringing in large quantities of supplies. Such materials as may be needed can be transported to the factories by truck. It will be possible to deliver cars by means of "driveaways" except to points far distant from factories.

### Tractor Prospects Improve

Reports are filtering in from tractor and farm machinery manufacturers that the winter months promise to bring an unexpectedly large volume of business from the rural districts. This is evidence of generally improved conditions in the agricultural sections.

The crop of rumors about impending mergers, combinations and consolidations is growing larger rapidly. A few of them are plausible but most of them are somewhat ridiculous. Reports of prospective combines of truck concerns

are most common and a majority of the companies in the business are mentioned.

While it will be found that few of the reports are founded on fact, it undoubtedly is true that consolidations are in the air and the next few months probably will witness several of them. One which promises success would bring together fourteen automotive concerns with physical assets valued at some \$50,000,000. Another even larger combine is contemplated.

## Stockholders Will Ask Bankruptcy for Revere

INDIANAPOLIS, Oct. 24.—Stockholders of the Revere Motor Car Corp. of Logansport have perfected an organization known as the Revere Stockholders' Protective Association. Officers of the organization are J. H. Reitemeier, president; Carl Rehm, vice-president; Dr. R. L. Swindler, secretary; David Middleton, treasurer.

Perfecting of the organization is the first step in the plans of local Revere stockholders to have the concern declared bankrupt, it is said. Officers of the stockholders' organization plan to file a petition in bankruptcy in the Federal court at Indianapolis, it was announced by officers.

The concern at the present time is in the hands of a receiver, and stockholders hope, by having the company declared bankrupt, to reorganize and put the plant on a paying basis and retain the industry in Logansport.

## Underwriters Suggest Fixed Depreciation Plan

NEW YORK, Oct. 24.—The policy under which the amount of insurance is automatically diminished monthly has not met with favor by the committee on forms of the National Automobile Underwriters Conference which is holding meetings in this city and which is now taking up the question of a policy which provides that the assured shall bear a portion of each loss.

A suggestion has been made that the conference adopt a plan of fixed depreciation and make its use mandatory for insurance purposes under a form of policy which could not be construed as "valued." If a monthly decrease in insurable value greater than the mandatory decrease were accepted by the assured, it is suggested that a reduction in rate might be allowed. This it is felt would win the moral support of automobile manufacturers and take a long step toward putting the business on a proper basis.

### U. S. TIRE ADDS NEW SIZE

NEW YORK, Oct. 24.—The United States Tire Co. has added one more size to the Royal Cord tires, this being 30 x 3½ in., the retail price of which is \$24.75. The new size is made of the same material and compound as is used in the larger sizes. Experiments have been going on for quite a long time.

## War Supply Transfer Totals \$118,264,808

### Majority of Motor Vehicle Surplus Goes to Other Government Agencies

WASHINGTON, Oct. 25—Figures prepared by the Director of Sales to-day show that vehicles valued at \$118,264,808 have been transferred from the War Department's surplus material to other Federal departments. The classification of vehicles includes motorized equipment which represented the largest percentage of vehicular equipment transferred. Transfers were made through the Transfer and Inventory Section office of the Director of Sales.

Vehicles turned over to other governmental agencies represented more than half the total value of army surplus material which was transferred. Sixty-six per cent of the surplus material which was transferred to the Department of Agriculture, cost the Government originally \$138,290,529.

The vehicles transferred to the Agriculture Department were for the use of the Bureau of Public Roads which in turn transferred them to State highway departments. The total value of vehicles given to the Agriculture Department by the War Department amounted to \$98,876,028.

The Treasury Department took vehicles valued at \$2,766,712. The Department of Commerce received vehicles valued at \$4,362,475; Navy, \$2,014,732, and the Post Office Department \$11,013,401. Aircraft material valued at \$9,548,853 was also transferred. The air mail service of the Post Office Department took \$2,919,547 worth of this equipment; Navy Department \$5,088,456 and the Department of Agriculture \$1,565,009.

## Shuler Axle Creditors May Reach Settlement

LOUISVILLE, KY., Oct. 24.—Assets of the Shuler Axle Mfg. Co., recently adjudged bankrupt in the Federal court, exceeded the liabilities by \$274,495.86, according to schedules filed with Judge George A. Brent, referee in bankruptcy. The total assets are listed at \$651,473.83 and liabilities at \$376,977.97.

Several days ago permission was granted to the receiver to operate the plant. Orders on hand, it was said, amount to \$3,000. The first meeting of creditors will be called for Nov. 2. It is believed a settlement will be effected and the operation of the plant continued.

### BARLEY HAS NEW TOP

DETROIT, Oct. 24.—Barley Motor Car Co. of Kalamazoo, manufacturer of the Roamer line, has added a new California top to its models which will sell for \$2,950 f.o.b. Kalamazoo. Shipments of the new model are being made now.

## Mileage Guarantee Opposed by Dealers

### Tire Association Calls Present Policy of Adjustments Wrong and Unfair

CLEVELAND, Oct. 24—Delegates from all parts of the country to the National Tire Dealers Association, in session here, brought the word that the retail tire business is on the upgrade and that in their judgment there is to be a gradual improvement for some months. Dealer after dealer reiterated the assertion that October has produced better sales than September and that September business was in excess of August.

The delegates adopted a series of resolutions, militant in tone, for the betterment of the dealer. They went on record in favor of a policy to put an end to deceptive advertising with respect to tires. They recommended the abolition of the mileage guarantee, the discarding of adjustments, the adoption of a distribution policy that will prevent manufacturers of cars dumping unused tires on the market at unfair prices, and important exchange privileges. Copies of the resolutions adopted are to go to every tire manufacturer.

#### Association Expands

In his annual report, Secretary Philip O. Deitsch pointed out that the association had but 10 cities represented less than a year ago when the body was formed, and that to-day 24 cities are affiliated and 53 are in process of being organized for representation.

One of the features of the meeting was the accessories exhibition. Trips to Akron and Kent were a part of the convention program.

William O'Neil, general manager of the General Tire & Rubber Co., Akron; C. S. Harris, vice-president of the Union National Bank, and C. C. Waddell of the Goodyear Tire & Rubber Co., were among the speakers during the sessions.

R. F. Valentine of this city was elected president, to succeed Thomas F. Whitehead of Chicago, who became a member of the board of directors. Frank Zeman of Chicago, was chosen vice-president and Deitsch was elected secretary-treasurer. These officers and the following, in addition to Whitehead, constitute the board of directors: R. J. Walters, Baltimore; E. P. Farley, Minneapolis; R. R. Dooley, Cincinnati, and A. B. Clark, Kansas City.

#### Resolution Adopted

The resolution in relation to mileage guarantees follows:

"Whereas, We are all agreed that the present policy of adjustments by tire manufacturers is erroneous, misleading and unfair to the legitimate tire dealer and ultimate consumer, and often used to the disadvantage of the tire manufacturer, therefore be it

"Resolved, That the manufacturers of quality tires should take prompt action to correct this evil by eliminating the mileage guarantee as it permits the 'snowbird' or 'gyp dealer' or 'broker' to prosper unfairly by

selling an inferior quality tire with an inflated list price and a long mileage guarantee to the trade at a big reduction from the inflated list price as an inducement to the trade, so when a tire proves defective and a customer returns with it, said dealer informs him that he will make an adjustment, but of course that said adjustment will be based on the list price. Therefore, the customer is compelled to accept said adjustment on that basis if he accepts it at all. This enables said dealer to make a profit on the adjustment at the expense of the user, therefore, be it further

"Resolved, That we believe a quality tire manufactured by a reputable manufacturer and sold by a reputable dealer needs no mileage guarantee. If the manufacturers do not deem it advisable to remove the mileage guarantee at this time, then we request that all adjustments be made through their authorized dealers who qualify as to their capability, and further be it

"Resolved, That said adjustments be based on the dealer's cost price of the tire, and why should not an authorized dealer make his prorated profit on what he purchased as a quality tire but which proved to be otherwise, the same as though he sold a new tire?"

#### Rubber Association to Act

NEW YORK, Oct. 27—The tire manufacturers' division of the Rubber Association of America will hold a special meeting at the Yale Club in this city to-day to consider a report made by a special committee which has been considering the subject of mileage guarantees on tires. The committee will make certain recommendations which the manufacturers will be asked to discuss.

A similar report was made some time ago but it was not entirely satisfactory to the majority of the manufacturers and the committee was asked to continue its investigation. While nothing can be learned in advance of the purport of the report there is a strong sentiment within the industry for the abolition of mileage guarantees.

Another subject which will be taken up at the meeting will be protection against price declines. This was first considered in September and since that time definite action has been determined upon.

## Dunlop and Michelin Fusion Conjectured

LONDON, Oct. 7—(By Mail)—The Dunlop Rubber Co., Ltd., announces that dividends on the 5 per cent cumulative preference stock and 8 per cent cumulative ordinary stock up to Aug. 31 will be paid after the annual meeting which has been postponed to the end of this month. The reason given is that "important negotiations of a nature advantageous to the company" are in progress but will not be completed before that time.

There is much conjecture as to the nature of the "important negotiations." The belief is expressed in some quarters that there is likely to be a fusion of Dunlop and Michelin interests. It is pointed out that the revised price lists of the two companies which have just been issued coincide in all respects as to prices.

## Durant Shipping Cars from Eastern Factory

### Deliveries to Purchasers Will Probably Begin on Large Scale Nov. 1

NEW YORK, Oct. 21—Production of the Durant Four now is well under way in the Long Island City plant of Durant Motors of New York. While this factory will supply only the eastern territory after the Lansing plant gets under way, cars now are being shipped to dealers in all parts of the country. They went to California by express and are said to have met with a flattering reception there. It is expected that deliveries to purchasers will begin on a large scale about Nov. 1.

Rapid progress is being made in building up a dealer organization. The main centers of population in the eastern territory now have been covered and many distributors and dealers have been appointed in other sections of the country. The Michigan dealer organization has been practically completed and orders have been placed for the delivery of 10,000 cars in that State in 1922.

The Collins Motor Car Co. has been organized in Boston to distribute the Durant and A. A. Leidermann, who has been Pierce-Arrow dealer in Utica, will handle the Durant in that city. The Boston company is capitalized at \$100,000 and is headed by Jerome T. Collins.

## Name Markin to Head Commonwealth Motors

CHICAGO, Oct. 24—Under a reorganization of the Commonwealth Motors Co., a new staff of officers has been elected headed by Morris M. Markin who entered the automotive field in Chicago several years ago with the Markin Auto Body Corp. It is understood these two companies will be combined under one roof at the Commonwealth plant in Joliet.

Other officers of the company are three of the older members of the Commonwealth organization. Amel Carlson has been made vice president and general manager, Edward J. Bouchard, treasurer and Walter L. Kroneberger, secretary and sales manager. The plant at Joliet is now running six days a week. The general offices have been removed to 1509 South Michigan avenue, Chicago.

#### SETS BOND IN PATENT APPEAL

CHICAGO, Oct. 24—The Stewart-Warner Speedometer Corp. will be required to file bond of \$150,000 pending action on the appeal of the company from the decision of Judge Carpenter in the United States District Court, of northern Illinois in the suit brought by Seager & Harrington, charging infringement of patent on the vacuum tank being manufactured and sold by Stewart-Warner.

## Requires Financial Aid of Bus Patrons

### Tidewater Lines, Inc., Makes Every Farmer Along Routes a Stockholder

WASHINGTON, Oct. 24—The Tidewater Lines, Inc., which operates fifteen passenger lines and ten freight trucks out of Washington over six routes reaching all points of Southern Maryland and down to Colonial Beach, Va. has inaugurated a plan for financing of passenger and cargo transportation lines which virtually makes every farmer making use of the service a stockholder.

In addition the company is given the hearty support of all of the town banks along the routes. These banks, realizing the need of this means of transportation, are often instrumental in getting the farmers to invest in stock through showing them that by aiding the company they are in turn also benefiting themselves through better service.

#### First Sell Banks

To date, there are 500 stockholders in the company, most of whom are farmers from Southern Maryland. The company realizes the importance of this financial support as a factor in determining the confidence of its patrons. Before opening a new route, it requires the entire support financially of all the farmers along that specific route. In a majority of cases, the local banks are first sold on the proposition. Sale of the stock is then carried on by the banks.

The governor of Maryland recently gave the company a franchise to operate its vehicles over the state roads. As a result of this permit, the company has effected a number of consolidations of competing truck and bus lines in Maryland, the most recent being that of the Arndt Transfer & Express Co., operating out of Baltimore. It has therefore been necessary for the Tidewater Lines to increase its capital to \$250,000 7 per cent. preferred with a \$100 par value and 12,500 shares of common, no par value.

## Stock Dividend Ruling Is Amended by Treasury

WASHINGTON, Oct. 24—Considerable progress has been made on the tax bill now before the Senate. The Senate has increased the income surtax rates from 32 per cent, as provided in the House bill, to 50 per cent, to meet the demands of the so-called agricultural bloc. It is expected, however, that this rate will be reduced to about 40 or 42 per cent in conference.

The Commission of Internal Revenue to-day issued a new paragraph to be added at the end of Article 1547 or Regulation 45, as amended by Treasury Decision 3206, which relates to stock dividends.

It reads as follows:

"Where the stock with respect to which a stock dividend is declared was purchased at different times and at different prices, and the identity of the lots can or cannot be determined, but the dividend stock issued with respect to such stock cannot be identified as having been issued with respect to any particular lot of such stock, then any sale of such dividend stock will be presumed to have been made from the stock issued with respect to the earliest purchased stock, to the amount of the stock dividend chargeable to such stock."

## Tractor Sales Increase in Southeast Territory

ATLANTA, Oct. 24—Tractor sales in the Atlanta territory the first two weeks of October were better than they have been at any time within the past year, due to the recent increases in the prices of farm products, principally cotton. Few large tractors are selling in the Southeast, but the demand for the smaller machines has been so great the past three or four weeks that some dealers are unable to secure all of the tractors of this kind they can sell.

Virtually all of the dealers throughout Georgia are reporting good business. Business in middle and eastern Tennessee has been good all summer and is unusually good at this time. In North Carolina and Alabama conditions have picked up materially the past three weeks and are getting better daily.

Sales in South Carolina, however, are still rather poor and have been all year. In Florida, and especially the southern part of the state, sales are at normal for the first time almost in two years.

## Mutual Truck Insolvent; Bank Appointed Receiver

SULLIVAN, IND., Oct. 24—At a hearing before Walter F. Wood, as special judge, the Mutual Truck Co. of this city was declared insolvent and on the petition of the Shuman-Pomeroy Co. of Chicago, with the Electric Steel Co. of Indiana, as the intervenor, the National Bank of Sullivan was appointed receiver.

Judge W. H. Bridwell, judge of the Sullivan circuit court, did not act, feeling that his interest in the Citizens' Trust Co., a creditor, disqualified him. In the presentation of the evidence, Luther Steele, vice-president of the concern, testified that the liabilities of the company amounted approximately to \$85,000. He was unable to state definitely the assets of the firm, but said the personal property alone would total near \$45,000.

#### NAME HOLMES RECEIVER

NEW YORK, Oct. 24—A petition in bankruptcy has been filed against the Holmes Motor Car Corp., of New York by three creditors who hold claims for about \$2,600. Judge Hahn appointed Z. W. Butler as receiver under a \$3,000 bond. The liabilities are estimated at approximately \$40,000 and the assets about \$6,000.

## Small Car Favored by Japanese Buyers

### Trend Is Also Shifting Noticeably From Enclosed to Open Models

LOS ANGELES, Oct. 24—Light, small cars continue to hold the Japanese automobile market, according to the latest advices received here. The trend from the large six-cylinder automobiles to the lighter types, which started following the imposition of the severe Japanese tax on automobiles, has become more and more marked in recent weeks.

The smaller cars, particularly those calling for the minimum tax, are moving fairly well, but the larger fours and sixes are finding few buyers. As a matter of fact, virtually the only sales being recorded in the larger cars are those being disposed of to government departments that do not have to pay the automobile tax.

There has been a very noticeable change in the demand for various body types in Japan in recent months. During the last six months open cars have become very popular in Japan, while formerly enclosed cars were all the vogue. Perhaps the change is due to the increasing number of owners who are driving their own cars and also because more motorists are taking trips into the country rather than confining their motoring to city streets. There are a number of instances reported from Japan where owners are selling their limousines and buying smaller cars with open bodies.

The Japanese body building trades are not enjoying a very healthy demand for their product, as the demand for the body of foreign manufacture is as insistent as ever. The Japanese body is declared to be usually equal, and often superior, in appearance to most foreign bodies, but the Japanese body builders seem unable to construct a body which will stand up for any appreciable length of time.

## Africa Sends Wichita Order for Ten Trucks

WICHITA FALLS, TEX., Oct. 24—Decided improvement in its export trade has been noted by the Wichita Motors Co., which has received an order for ten 1½-ton trucks, pneumatic tired, to be shipped to the Gold Coast of Africa. Inquiries from many foreign countries are now being received and J. G. Culbertson, the company president, declares that export sales will continue to attain a better volume.

Nearly all motor transportation facilities in foreign countries depreciated during the war and owners now are discarding them for those of modern design. Culbertson added that the countries of South America, Africa and the Far East are purchasing practically all of the trucks from United States firms.

## Paris Show Promises Good Business Year

### Public Responds to Lower Prices —Repeal of Gasoline Tax Boosts Sales

PARIS, Oct. 16 (*By Mail*)—Manufacturers generally are satisfied with the results obtained at the Paris automobile show. Sales have been good in the lower and medium price class cars and moderate in the high class cars. When the show opened makers were nervous regarding results, for they had made a considerable effort to attract customers by better value and lower selling price, but they had no assurance that the public would respond.

It seems to have been realized that no further price reductions are possible, and as a consequence buyers' resistance has broken down and sales have taken place. This movement was accelerated toward the end of the show by a Government announcement of the repeal of two cents per litre on the state gasoline tax, to go into effect immediately, followed by another reduction of one cent on Jan. 1.

Owen Clegg of the Talbot-Darracq Co. stated that business had been so good they would have to start a double shift in the machine shops in order to keep pace with deliveries. Isaac Koecklin of the Peugeot Co. declared that the results had been surprisingly good, sales having been brisk on the whole series of models. In his opinion the show had surpassed expectations.

The Fiat Co. reported good business on the 10 hp. model. Louis Delage indicated that his small 11 hp. four-cylinder had sold well and there was a healthy outlook for the other types. Lancia reported good sales. Citroen is said to be fully booked up on his two lower price models.

It is believed generally that if the political situation remains clear the coming year will be a very successful one for French manufacturers. Gasoline prices are going down, tires are dropping, there will be no increased taxation on automobiles, and selling prices have stabilized.

### S. F. Bowser Absorbs Richardson-Phoenix

MILWAUKEE, Oct. 25—The Richardson-Phoenix Co., which manufactures automatic lubricating devices and appliances for filtration and reclamation of lubricants at a large plant in this city, has been consolidated with the S. F. Bowser Co. of Fort Wayne, Ind. The deal involves more than \$1,000,000. The combined companies have assets exceeding \$10,000,000.

J. William Peterson, president of the Milwaukee company, becomes vice-president of the Bowser company. S. B. Bechtal, vice-president and general manager of Bowser, will assume the same duties at the Richardson plant, succeeding Louis

### EPIGRAMS THAT RIDE WITH JOHN N. WILLYS

NEW YORK, Oct. 24—John N. Willys, who has devoted much of his time for months to addressing Willys-Overland dealers in all parts of the country, has developed a reputation as a maker of epigrams. Here are a few of those he used in one of his recent dealer addresses:

"I take a train from New York for Toledo that gets in at 4:40 a. m. so I can get an early start instead of the train that gets there at bankers' hours."

"I'm never going to quit when business is bad."

"I'd rather work out than rust out."

"The public had me broke a year ago, and it saved me from a lot of 'touches' and explaining."

"Three weeks out of every four I am at the factory, and the other week I'm out on the road helping the dealers."

"My dealers have always been pals, not forced to walk on the bridge of formality to reach me."

"It takes a strong man to throw a bull, but we've had too many conversational bull throwers in the motor industry."

E. Strothman, who is seriously ill and will retire to take a long rest. The officers of the Milwaukee plant will be retained. It is understood that the Richardson-Phoenix Co. will retain its identity with Peterson continuing as president.

### Wins \$417,477 Verdict in Columbian Suit

EAST PALESTINE, OHIO, Oct. 25—George W. Stevens has been given a verdict for \$417,477 in a suit against the Columbian Tire & Rubber Co. for breach of contract. The jury found that Stevens made a contract with the company to act as general sales manager for which he was to receive 5 per cent commission on the net sales of tires and tubes. The contract was signed May 1, 1918 and was broken, according to the plaintiff, on Nov. 13, 1919. It was the decision of the jury that Stevens was entitled to his commission on sales amounting to \$7,768,550 from Nov. 13, 1919 to May 1, 1923 plus an increased salary and a bonus.

### STUDEBAKER CUTS OUTPUT

SOUTH BEND, IND., Oct. 25—The Studebaker Corp. has temporarily curtailed its output in connection with the adjustment of winter schedules. President Erskine states that production in all plants during the fourth quarter is expected to exceed 60 per cent of the third quarter.

## New British Sunbeams Have Overhead Valves

### Changes Perfected in Engine— Vauxhall Introducing Model for Small Bodies

LONDON, Oct. 14 (*By Mail*)—The British Sunbeam cars of all sizes for 1922 will have push-rod operated valves in the head. The range will consist of the existing 16 hp. four and 24 hp. six-cylinder models (3½ x 5½ in.) with new engines and an entirely new model of 14 hp. with four cylinders 2 13/16 x 4½ in., the engine being a unit construction with the three-speed gearset, which is an innovation for Sunbeam.

Vauxhall is also introducing a 12 hp. model for small two and four-passenger bodies, the engine having a bore and stroke of 2 15/16 x 5½ in. But neither this nor the new small Sunbeam will be of a popular price, for they are both to sell with a four-passenger body at \$3,700 to \$4,000.

Standard will also supplement the successful 12 hp. overhead valve chassis by one of 8-10 hp. with a four-cylinder, 2 7/16 x 3½ in. L head engine. The new air-cooled Armstrong-Siddeley will not be at Olympia, but an example will be in London during the show; this model, by the way, will not be sold as an "Armstrong-Siddeley," but will be given another name to distinguish it from the six-cylinder cars.

Nor is the 20 hp., four-cylinder Rolls Royce to be expected at the show; in fact, it is questionable whether a new type will supplement the 40-50 hp. six for some time to come. Present indications, nevertheless, point to there being at Olympia a record number of new models by well-known makers and, without doubt, the general trend is all toward smaller and lighter cars, more economical to run, if not of low first cost.

### Firestone Loses Action Brought by Cotton Mill

CHESTER, S. C., Oct. 24—The Marlboro County Court has given the Marlboro Cotton Mills a verdict for \$121,392 in its suit against the Firestone Tire & Rubber Co. to enforce compliance with a contract for the purchase of tire fabric. The contract was made in 1919 and under it the tire company was to pay \$1.55 a pound for the fabric. When the decline in prices came, it was alleged, the Firestone company refused to accept the larger part of the fabric. This refusal resulted, the cotton mills contended, in the loss of the amount of the verdict.

The Firestone company was not represented in court and ignored the trial, claiming that the South Carolina courts had no jurisdiction in the case. It was shown at the trial, however, that the tire company has a distributing base at Columbia and a traveling representative in the State.

## Price Uncertainty Felt in California

### Prospects Fail to See Rock Bottom Reached and Adopt Waiting Attitude

SAN FRANCISCO, Oct. 24—Is the promise, freely made by some dealers to purchasers of cars, that there would be no more price cuts and that the price paid at that moment by the buyer was the ultimate, rock-bottom, absolutely final figure, acting as a boomerang and coming back to knock the business of these dealers in the head?

Many of the dealers and distributors on the Pacific Coast are beginning to think so, and many of them are referring with regret to the congratulatory words they said to buyers a few months ago, relative to the buyers having been fortunate in waiting until the "last price cut."

### Public Always Dubious

To tell the plain truth, a good many of the "wiser" dealers are of the opinion that the public has reached the point where it never will cease expecting further price cuts, and that this is one of the strongest, if not the very strongest, reasons that the prospects are not coming forward to buy new cars. It is certain that the majority of men who now own automobiles in northern California—and, probably, in southern California as well—are spending real money in repair shops to have their cars rehabilitated and kept in the best possible condition, so as to get every remaining mile out of them without buying new cars.

One man closely connected with the automotive industry, both as to passenger cars and trucks, and, to some extent with tractors, summarizes the situation at the middle of October as follows:

"I for one—and there are scores of others in the industry who hold the same belief—am firmly convinced that there will be no general automobile buying in northern California until the people are assured that the bottom in prices has been reached. When this bottom is to be reached is a matter for the manufacturers to decide and just how the people are to be convinced that it has been reached, is a difficult problem which the automobile dealers must solve."

### Liquidation Complete

Men who have to have automobiles for their business or industrial interests are buying them; others are making their present cars do. There is no doubt about this being the prevailing condition from the Tehachapi Mountains north to the northern boundary of the State, and registration figures indicate that the same condition prevails in southern California.

Indications in general throughout the State are that liquidation is virtually completed that the farmers, and consequently, the merchants and other business men in the agricultural districts, have received a large part of the money for their crops, and dealers and distrib-

## PHILADELPHIA THEFTS MAKE HIGHEST RECORD

PHILADELPHIA, Oct. 24—Motor cars valued at more than \$4,000,000 and numbering 2510 units have been stolen during the year in this city, nearly doubling last year's theft losses here. The year 1921 will stand out as a car theft record year in Philadelphia. Carelessness, police officials assert, is the largest factor in rolling up the record loss of motor cars.

During the period of Jan. 1 to Oct. 31, 1920, 1518 cars were stolen, valued at \$2,303,000.

Against the losses reported this year, the figures show 2112 cars, valued at \$3,685,348, were recovered. During the same period in 1920, 1651 cars valued at \$2,548,989 were recovered.

utors insist that sales will show a much better proportionate figure for the last five months of 1921 than they did for the first seven months. The retail districts undoubtedly are showing some improvement, but whether it be from the fact that money is coming in to the farmers and thus to other buyers, or whether it is the result of intensified selling campaigns during the preceding six months, it is hard to determine.

## Franklin Completes New Inspection Plan

SYRACUSE, N. Y., Oct. 24—The details of the H. H. Franklin Mfg. Co.'s monthly inspection plan for passenger cars are now complete and Franklin dealers are putting it into practice. The various items to be inspected are listed on an inspection report form which has been designed by the company.

No operations other than those listed are undertaken. If any repairs are found to be necessary the matter will be taken up with the owner. A post card form requesting the owner to bring his car into the service station for inspection has also been designed. Three monthly inspections are to be given free of charge after the sale of the car, but a small charge will be made for subsequent inspections.

### ATWATER CLOSES DOWN

SOUTHINGTON, CONN., Oct. 24—Practically the entire plant of the Atwater Mfg. Co. has been closed down. The plant has been on a five-day per week working schedule, but because of the small number of orders on hand it was decided to lay off the help until more orders are received. A few men will be employed to keep the machines in condition. The factory has been doing special drop forge work for the Ford Motor Co.

## Records Shattered by Goodyear Truck

### Makes Better Time Between Cali- fornia Cities Than Do Fast Trains

AKRON, Oct. 24—The Goodyear six wheeled motor truck, the first multiple wheeled motor vehicle to make a trans-continental run from Akron to Los Angeles, has shattered all motor truck records for negotiation of the distance between San Francisco and Los Angeles, according to word received here by officials of the company.

The huge six wheeler made the trip of 420 miles in 14 hours and 40 minutes, at an average speed up and down hill of 29 miles an hour. The truck carried five tons of freight on the trip. The best previous truck record for the distance was made by a 3½-ton truck which averaged 24 miles an hour.

Goodyear officials say the truck made the trip faster than the fast trains of the Southern Pacific Railroad, which take 14 hours and 50 minutes for the San Francisco-Los Angeles trip. On the trip the six wheel truck had to climb a grade of 1700 feet in the first 27 miles, and in the next 40 miles climbed to an elevation of 4230 feet above sea level.

Compared with railroad time for trips of similar distances, it is stated, the Goodyear truck on the basis of its Pacific Coast performance could carry freight from New York to Montreal and deliver it at its destination in only an hour's more time than is occupied by a fast passenger train in going from New York to Montreal.

Based on an average speed of 29 miles an hour, the Mississippi River can be brought within two days' journey by motor truck of either the Atlantic or Pacific seaboard.

The Goodyear truck on its run from Akron to Los Angeles made the distance of 2980 miles in 7 days and 35 minutes of actual running time. This is a new record for the distance. The truck rode on 8 inch tires.

## Rost Is President of Richelieu Motors

ASBURY PARK, Oct. 24—The Richelieu Motor Car Corp. announces that its officers and directors are as follows:

President, N. G. Rost, former sales manager of the Duesenberg Motors Corp.; vice president, S. A. Reeves, vice president Merchants National Bank of Asbury Park; treasurer, R. G. Poole, president First National Bank of Farmingdale, N. J.; Donald Symington, president Lock Insulator Co., Gordon Grand, president, New Jersey Registration & Trust Co. of Orange; E. H. Croft, president of the Ker-O-El, Cleveland; W. F. Quinn, president of Quinn & Quinn, Inc., and a member of the New York Board of Aldermen.

# Hoover Urges Human Touch in Business

Sends Message to Editors of Business Papers, Who Hold Annual Convention

CHICAGO, Oct. 26—Herbert Hoover, Secretary of Commerce, who has been holding monthly meetings in Washington with the editors of business papers representing all industries, suggested in a message to the editors who are holding their annual convention here this week, that industrial problems be considered from a human rather than a material standpoint. He said:

"I have appreciated the opportunity given me in the monthly meetings to express the policies of the Department of Commerce with regard to some of the pressing industrial questions before us, and I cannot but feel that if these problems are considered as human and not as material questions we can find their solution. . . . There must be in our discussion of these questions the dominating thought that the better control of economic forces is in fact simply the better comfort of the country."

The editors in a symposium on the present status of basic industries gave a vivid picture of industrial conditions.

## Steel Future Uncertain

A. I. Findlay, editor of *Iron Age*, reported that the steel industry had turned the corner in July and to-day is at 40 to 45 per cent of its war peak capacity. Since July there has been an increase from 22 per cent to 45 per cent. Prices now are 31 per cent above the 1913 average. The future of the steel industry is still uncertain, he said, but it is expected that production will reach 60 per cent of war peak capacity during 1922.

The electrical industry in certain departments, such as manufacture of motors and meters, is at 60 per cent capacity, and the average consumption of electric current this year exceeds that of 1919, according to F. E. Watts of *Electrical Record*. The sales through electrical jobbers are but 50 per cent of last year. Business has been improving in the last three months.

## Building Costs High

In the building construction field building contracts for 1921 are 83 per cent of those for 1913 and construction cost is 34 per cent below the high war peak and 30 per cent less than a year ago, W. W. De Berard of *Engineering News-Record* stated. In such public works as water and sewer enterprises, he said, September of this year was double that of a year ago. He also stated that construction costs are still 80 per cent above the 1914 price level and believes that reduction in labor costs in 1922 will greatly stimulate building.

The leather tanning industry is at 50 per cent capacity, according to James H. Stone of *Shoe Retailer*. Deflations in the leather trade started in 1919. Calf skins, that sold during the war at \$1 per pound, brought 13 cents this year. Some grades of cow hides in July, 1921, sold as low as 3 cents a pound.

An interesting angle on the agricultural situation was given by C. V. Gregory of *Prairie Farmer*, who showed that to-day 59 per cent of the farms in the country are unencumbered, and of those that are the value of the mortgage is only 29 per cent of the farm value.

David Beecroft presented a summary of the automotive industries.

F. M. Feiker, assistant to Secretary Hoover, told of the endeavors of the department to effect standardization in all industries in order to reduce living costs.

The value of the business paper to the daily press was analyzed by Glenn Griswold, financial editor of the *Chicago Journal of Commerce*, who looks to the business press for the correct summary of conditions in all industries. The daily press not only asks for such assistance but wants it. Financial editors are now quoting at length from the business press, giving conditions in most industries, and are desirous of going still further in this regard.

## Automobile Reimports Show Gain in September

WASHINGTON, Oct. 24—The importation of automobiles from foreign countries into the United States totaled 69, having a value of \$97,365, during September, according to an announcement of the Bureau of Foreign and Domestic Commerce. This compares with a total of 201, valued at \$191,707, during the same month last year. For the nine months of this year, the importations have been 399, with a value of \$698,771, against 746, valued at \$794,910, during 1920.

The reimports of automobiles show something of a gain in September of this year over the same period of last year, although this is not true of the nine-month period. The comparative figures are:

	No.	Value
September, 1921.....	443	\$695,586
September, 1920.....	302	391,170
Nine months, 1921.....	3,182	5,021,757
Nine months, 1920.....	4,390	7,196,283

## G. M. C. Remains Silent On Scripps-Booth Plans

NEW YORK, Oct. 24—Officials of the General Motors Corp. have declined to make any statement whatever concerning the action taken at their meeting in Detroit last week in reference to the future of the Scripps-Booth division. It is understood that there is a strong probability the company may be sold as a going concern instead of being liquidated. A decision is expected in the near future.

# Used Car Trades Cost Indianapolis \$193,000

Only Four Dealers Made a Profit, Aggregating \$2,300—State Conditions Similar

INDIANAPOLIS, Oct. 22—Thirty-six Indianapolis automobile dealers lost a total of \$193,000 in the trading and selling at retail of 2972 used cars since Jan. 1. Only four of 40 automobile dealers realized a profit on the handling of used cars in that same period. Their combined profits aggregated \$2,300.

That is the graphic story of the "used car situation" in Indianapolis. It is a pretty fair barometer of the used car situation in the state. In one corner of the state, New Albany, one dealer has 57 used cars on hand. No other dealer in the city has more than 10.

In Evansville, one dealer has 61 used cars; in Terre Haute several have as many as 35. Fort Wayne, Logansport, Lafayette, South Bend, Marion all report one or more merchants heavily loaded. In a few spots where the dealers have been almost 100 per cent in their association co-operation, is the used car situation good, or rather, is not menacing.

Everywhere the dealers are seeking the "answer," which seems to account for the unusual interest that is being taken in the "Indianapolis plan" of harmonizing policies in the trading of cars. One Indianapolis new car dealer had an opportunity to dispose of a used car stock. He exchanged his 14 used cars for a farm of 160 acres in Jackson County.

## Gasoline Consumption Reaches High Record

WASHINGTON, Oct. 24—A new high record in gasoline consumption was established in August when 503,000,000 gallons were used, according to an announcement by the Bureau of Mines. Although the average daily production in August of 13,921,000 gallons was 385,000 gallons more than in July, total stocks on Aug. 21 amounting to 567,645,000 gallons showed a decrease of 116,000,000 gallons during the month, according to the figures.

Exports of gasoline in August totaled 47,803,000 gallons, or 75 per cent, more than in July. Total production for the month was given as 131,577,000 gallons.

## NO CHANGE IN FRANKLIN

SYRACUSE, Oct. 26—The Franklin Automobile Co. has informed its dealers that the present model, without change, will be featured at both the New York and Chicago shows. The company states that Franklin cars on sale next spring will be of the same design as those now on the market. New York led in sales of Franklin cars for the contract year ending Sept. 1. Chicago was second, Boston third, San Francisco fourth and Los Angeles fifth.

## Factories Continue Heavy Production

Output Governed by Sales—Business, in Instances, Exceeds That of Summer

DETROIT, Oct. 25—Despite the fact that all factories are operating strictly on a sales basis, heavy production continues to be the rule, and with some companies, notably the producers of higher priced cars, business is running along as strongly as during the summer months, and in a number of instances better.

This is due in large part to the intensive selling efforts undertaken by the more aggressive factories. In these plants there is to-day a higher priced sales organization than ever before in the history of the industry.

### Follow Ford Plan

The Ford organization is, perhaps, the most highly developed, for the reason that Ford went after sales through close field analysis long before most of the other companies realized the value of it. Now, however, the Ford system is being closely followed right through to the highest class field.

Territorial representatives are making their strongest efforts to get business in shape, not so much for the balance of this year as for 1922. Investigations in the field are being carried on to indicate possibilities for next year's business and general satisfaction is expressed at the results disclosed.

Not only are the possibilities of territories being analyzed, but the dealer organizations are being studied to discover their ability to represent the factory fairly in the keen competition certain to develop in the coming year. Factories are working with might and main to strengthen their retail selling forces before the early buying starts.

Every effort at co-operation will be made by manufacturers to prevent flooding the market, but at the same time they will demand that their share of business be gathered in by every representative. No dealer will be assigned more than he can do, but each will be given the definite proposition of meeting the actual business there is for him in his field.

### Used Cars Left to Dealers

Factory officials realize that the used car situation has become acute owing to the elimination from the market this year of the usual used car buyer. With a return of better industrial conditions as promised in 1922, this condition is expected to right itself rapidly, and coping with the situation will be left for the most part to the individual dealer.

Factory executives look to the East and the South as the big sales field for 1922, with a good steady business in the Mid-West and on the Pacific Coast. More attention will be paid to the selling of first car owners than at any time in

## INAUGURATE BUS LINE FOR LONG DISTANCES

CHICAGO, Oct. 24—A new idea in long distance transportation of tourists by means of motor buses was put into effect yesterday by the T. & S. Tourist Co. of this city when it started four White 10 passenger buses and a fleet of privately owned touring cars for New Orleans.

The caravan will cover 1135 miles on the journey from the Great Lakes to the Gulf. There will be a one-day stopover at Mammoth Cave and sight seeing tours in the principal cities along the way. Entertainments by Chambers of Commerce and civic organizations will be provided in all the larger places. The caravan is scheduled to reach New Orleans Nov. 2.

the industry, producers realizing that sane progress can only be made by enrolling new owners.

### Oakland on New Schedule

Oakland Motor Car Co. will enter upon a schedule of 100 cars a day in November, after a lull in manufacturing in the last two weeks of October. During this period the factory organization has been reduced to a minimum, but officials declare that this action was taken because of factory conditions rather than a lack of business.

In restarting upon a heavy schedule, officials say that this has been necessitated by increased business in all parts of the country, the East and South leading. All models are included in the orders, with a predominancy toward the enclosed. With the scheduled business November is expected to exceed September, which had been the record month of the year.

Despite conditions in October it was said this month will show a large increase over business in October, 1920.

Packard Motor Car Co. in the two days immediately following its price reduction on the single-six model, reports shipments averaging 200 cars a day. The sales response has been general, officials declare, orders not being limited to any one section of the country. Enclosed cars are meeting with biggest demand. Of 339 cars shipped yesterday, 159 were sedans and 39 coupes.

### KELSEY INFRINGED PATENTS

DETROIT, Oct. 26—Federal District Court here has decided patents of the Universal Wheel Co. have been infringed by the Kelsey Wheel Co. The decision affects royalties on rims manufactured by Kelsey prior to 1917, according to Kelsey officials. An appeal to the Supreme Court will be taken. John Kelsey, president, says the total sum involved is nominal and has been covered by a reserve for some time.

## Says New York Thefts Are Largely Frauds

Loose Insurance Methods Blamed in Survey Made by City Official

NEW YORK, Oct. 25—The startling statement that 80 per cent of the automobiles reported stolen in this city are fictitious or were disposed of for the purpose of collecting insurance on them was made by David Hirshfield, commissioner of accounts, in a report on an investigation into automobile insurance ordered by Mayor Hylan. He declared he had discovered that automobile insurance companies made no effort to learn whether an applicant for a policy actually owned a car or whether his car was of the value stipulated in the policy.

### Companies Are Lax

Hirshfield stated that one of his agents applied for a \$500 policy on an automobile that never existed. A few days later he received the policy. This incident was followed by another of the same character in which a policy for \$700 was issued by another company. A similar plan was tried a third time with a third company with equal success, according to Hirshfield.

The commissioner asserted that although the three policies had been issued more than six weeks no official from any of the insurance companies had called on the policy holders to request an inspection of the cars.

"There was a report the other day," Hirshfield stated, "to the effect that 160 cars were stolen in this city in 12 days. My investigation convinced me that most of these cars were not stolen at all. The owners of many of them, I believe, merely threw them into the river or disposed of them in places outside of the city and then collected insurance on them. Such loose methods on the part of insurance companies are a temptation to the dishonest."

## Johnson Motors Formed Through Consolidation

SOUTH BEND, IND., Oct. 26—Consolidation of the Johnson Motor Wheel Co. of Indiana and the Quick Action Ignition Co., both of this city, as the Johnson Motor Co. of Delaware has been completed. While substantial orders for the old lines are being received, the company is developing a light twin cylinder outboard motor which will fill in between seasons.

Operations are directed by Charles Kratsch as vice-president and general manager. He formerly was manager of the Sumter division of the Splittorf Electrical Co. His chief assistant is P. A. Tanner, former secretary of the Splittorf company, for which he developed a service organization.

Albert Erickson is in charge of experimental and development work but L. J. Johnson remains as head of the engineering department.

## Orders Public Sale of Owen Magnetic

Will Be Sold in Lots If Offering  
as Unit as First Made Is  
Unsuccessful

WILMINGTON, Oct. 24—Receivers for the Owen Magnetic Motor Corp. have been directed by a court order to sell at public auction all the assets of the company at the main offices at Forty Fort, Luzerne County, Pa., at 11 a. m., Nov. 5. The sale will include land, buildings, parts and materials.

The plant consists of a one-story concrete building of saw tooth construction, 600 x 80 ft., and another of the same construction 264 x 80 ft., as well as a frame structure 109 x 46 ft. used as a stockroom. There are several smaller buildings. The machinery and tools are of the latest design and include equipment of all kinds. The inventory consists of large stocks of parts, a considerable portion of which can be used only in the manufacture of the Owen Magnetic car or one of similar design, as well as large quantities of high grade steel.

The property will be offered first as a unit, and if there are no bidders it will be sold in lots.

After the assets are sold, proceeds will be divided among the creditors at the direction of the court and the affairs of the company will be wound up.

## Locomobile Changes Personnel of Branches

BRIDGEPORT, CONN., Oct. 25—Several changes in the personnel of the Locomobile Co. have been made since the return of former executives to their old posts. They have resulted from a decision by the company to merchandise through its own factory branches.

Locomobile branches have been re-established in Los Angeles under the direction of T. D. Swayne and in San Francisco under C. A. Kingsley. C. R. Norton, who has been in charge of both these branches with headquarters in Los Angeles, has been relieved.

Similar changes have been made in the Chicago organization and W. S. Porter has returned to that city from the Boston branch, where he was general manager. He succeeds H. S. Norton.

W. S. Horner has succeeded Oscar Coolican as branch manager in Philadelphia.

## McGraw Is Readjusted with New Directorate

CLEVELAND, Oct. 27—Readjustment of the financial affairs of the McGraw Tire & Rubber Co. has been completed by the reorganization of the board of directors to include representatives of banking interests and merchandise creditors who will co-operate with the management in the conduct of the business.

The plan does not call for any change in the company personnel or new financing.

President John Morgan states that a satisfactory settlement has been made on all merchandise contracts. Indebtedness to banks and merchandise creditors has been reduced \$400,000 since the plan became operative. Discounts are being taken on current purchases and the company has ample cash to provide working capital. The McGraw plant is now operating two 10 hour shifts and it is asserted that orders on hand soon will necessitate an increase in production.

## Census Bureau Issues New General Schedule

WASHINGTON, Oct. 24—Director of the Census William M. Steuart has issued the general schedule for manufactures for the census of 1921 which was prepared in co-operation with the committee created at the July conference in Washington of trade and craft associations with Secretary of Commerce Herbert Hoover and officials of the census bureau.

Because of its simplicity the new schedule differs from past schedules and also varies with regard to the amount of information called for. As outlined the new schedule covers the following items: Names and particulars of establishments as to location and lines of products; persons employed as salaried employees, including managers, clerks, etc., and total salaries paid; wage earners, including piece workers and total wages paid; time and operation and products which will be detailed for the particular industries.

J. Walter Drake of the National Automobile Chamber of Commerce represents the automotive trade in its relations with the Department of Commerce in this activity.

## BRISCOE & STAHL ENLARGES

DETROIT, Oct. 26—The Briscoe & Stahl Co. has increased its capitalization to \$205,100 and will enlarge its consulting engineering business to include representation of foreign companies in the automotive field both as buying and selling agents. The consulting work of the company will also be extended to include other fields than automotive. The officers of the company are Benjamin Briscoe, formerly of Briscoe Motor Co., Jackson, Mich., and Rodalphe Stahl.

## WILLYS SHIPS 86 CAR LOADS

TOLEDO, OHIO, Oct. 24—Eighty-six carloads of Overland and Willys-Knight cars have been shipped from the factory here in a solid train to Los Angeles. The value of the shipment has been placed at \$547,000.

## DRUMPLEMAN LEAVES HUDSON

DETROIT, Oct. 27—W. J. Drumpleman, for three years assistant sales manager for the Hudson Motor Car Co., has been appointed assistant to Eddie Rickenbacker, director of sales, advertising and service of Rickenbacker Motor Co.

## Durant Engine Order Increases Employees

Continental Will Add 2,000 Men  
at Muskegon Through  
\$12,000,000 Contract

DETROIT, Oct. 26—Orders for \$12,000,000 in engines placed by Durant Motors with the Continental Motors Corp. will result in the addition of 2,000 men to the force at the Muskegon plant. Production on the new orders will be started at once, first deliveries being to Long Island City and later to Lansing, Oakland, Cal., and Toronto as those plants get into production. The Lansing factory begins operations in November.

Engines have been going forward to the Long Island City plant for some time on a tentative contract basis. With the Durant business and the general improvement in automobile sales, Continental expects to have the Muskegon plant on 100 per cent operation basis by summer.

The engine is a special type designed by Durant engineers which will be made to specification by Continental. These will be Fours exclusively. The Durant Six will be made by Ansted as stated recently.

## Automobile Shortage Is Seen in Australia

WASHINGTON, Oct. 24—Recovery has been made in automotive exports in several sections of the world, according to Gordon Lee, chief of the automotive division of the Bureau of Foreign and Domestic Commerce. Because of present demands, he states, there will be a shortage of automobiles in the district served by Melbourne, Australia, as an automotive distributing center.

Lee also states that there is a recovery in South Africa where gradually improving conditions are being reflected in car sales both to dealers and users, and where conditions are reported as approaching normal. Comment is also made on the fact that that automotive exports to Mexico of passenger cars for the first eight months of the current year totaled 4,753 as against 1,955 for the corresponding period of last year.

## Hoover Asks Industry for Advisor in Strike

DETROIT, Oct. 27—Secretary of Commerce Hoover has asked the automotive industry to designate a representative to act as his adviser in connection with the mobilization and allocation of motor trucks in the event of a railroad strike. It is understood that Roy D. Chapin, president of the Hudson Motor Car Co., and an officer of the National Automobile Chamber of Commerce, may accept the appointment as a patriotic duty to assist the nation as was done during the war.

## Prices of Hupmobile Return to Old Level

### General Cut Made in May Followed by Partial Reductions in September

DETROIT, Oct. 26—A downward revision has been made in Hupmobile prices by the Hupp Motor Car Corp. A general cut in prices was made last May and in September there was a further reduction in the coupe and sedan. The reductions are as follows:

	Old Price	New Price
2 passenger.....	\$1,485	\$1,250
5 passenger.....	1,485	1,250
Coupe .....	2,200	2,100
Sedan .....	2,250	2,150

With this revision prices are now down to the 1917 level.

### BRITISH FORD DROPS

LONDON, Oct. 4 (By Mail)—For the second time within a few months Ford prices are down, this time from £5 to £65, the average rate being £30. While this step is approved by the public and ultimately by dealers, the latter are affected through its not being the Ford practice to credit dealers with these reductions on unsold stock. The price of the Fordson tractor was recently cut to £205 from £225.

### COLE IS \$65 LOWER

INDIANAPOLIS, Oct. 24—The Cole Motor Car Co. announces that effective Oct. 27 its model No. 870 touring car will sell for \$2,485. This is a reduction of \$65. The prices on all other models have been reduced accordingly.

## Federal Price Cuts Average 22 Per Cent

DETROIT, Oct. 25—Price cuts running as high as \$850 are announced by the Federal Motor Truck Co. The average is about 22 per cent on all models and the reduction is the fourth within the last two years. The prices follow:

	Old Price	New Price
1 ton.....	\$2,500	\$1,800
1½ ton.....	2,775	2,175
2 ton.....	3,025	2,425
3½ ton.....	3,950	3,150
5-6 ton.....	5,350	4,550

Reductions of \$600 and \$800 have been made on the light and heavy duty tractors.

### NEW THOMART PRICES

KENT, OHIO, Oct. 24—The Thomart Motor Co. has reduced its price on the Akron Multi truck, model 20, capacity 1½ tons, from \$1,995 to \$1,695.

### HART-PARR REDUCES

CHARLES CITY, IOWA, Oct. 26—Effective Nov. 1, the Hart-Parr Co. will make a substantial reduction in the price of both models of its tractors. The price

of the Hart-Parr "30," which for the past year has retailed at \$1,595 f.o.b. factory, is now listed at \$1,295, cash, f.o.b. factory. The Hart-Parr "20," which was reduced June 1 from \$1,195 to \$995 cash, is now listed at \$945 cash, f.o.b. factory. These prices are the lowest at which these Hart-Parr tractors have ever been sold.

## 6-Cylinder Packard Makes \$625 Reduction

DETROIT, Oct. 24—The Packard Motor Car Co. announces a reduction of \$625 in the prices of all models of its six-cylinder car, effective to-day. The prices follow:

	Old Price	New Price
2 passenger touring...	\$2,975	\$2,350
5 passenger touring...	2,975	2,350
Coupe .....	3,750	3,125
Sedan .....	3,975	3,350

When the single six was brought out a year ago the price was \$3,640. This was reduced to \$2,975 on Nov. 1, 1920. The new price therefore represents a reduction of \$1,290 in less than a year. The price of the sedan was reduced on July 5 last from \$4,250 to \$3,975.

No change has been made in the price of the twin six models.

### DIAMOND T CUTS

CHICAGO, Oct. 25—Price reductions announced by the Diamond T Motor Car Co. on all its models are as follows:

	Old Price	New Price
1 ton.....	\$2,500	\$1,975
1½ ton, model F S.....	2,960	2,525
1½ ton, model T.....	2,650	2,250
2 ton.....	3,285	2,650
3½ ton.....	4,675	3,750
5 ton, model E L.....	5,400	4,325
5 ton, model S.....	5,650	4,500

### STERLING REDUCES

MILWAUKEE, Oct. 25—The Sterling Motor Truck Co. announces the following price reductions:

	Old Price	New Price
1½ ton.....	\$3,200	\$2,885
2 ton.....	3,500	3,085
2½ ton.....	3,650	3,290
3½ ton.....	4,600	4,325
5 ton, model 5W.....	5,500	4,950
5 ton, model 5C.....	6,000	5,500
7½ ton.....	6,500	6,000

### REDUCE HAL-FUR TRUCKS

CLEVELAND, Oct. 24—The Hal-Fur Motor Truck Co. announces the following downward revision in its prices:

	Old Price	New Price
1½ ton.....	\$2,350	\$2,200
2½ ton.....	3,250	3,000
3½ ton.....	4,250	4,000

### ATLAS PRICE DOWN

YORK, PA., Oct. 24—The Atlas Truck Corp. announces a reduction in its 1-ton model from \$1,550 to \$1,185.

### G. W. W. TRUCK REDUCED

HENDERSON, IOWA, Oct. 26—The Wilson Truck Mfg. Co. has reduced the price of the G. W. W. truck, 1½-tons, from \$2,100 to \$1,950.

## BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.

During the past week the local money market has shown signs of marked ease. The week's range for call money was 4 per cent to 5½ per cent in comparison with a range of 5 per cent to 6 per cent for the previous week. Renewal rates ranged from 4 per cent to 5½ per cent with 4½ per cent ruling, and accommodations were arranged in the "outside" market at as low as 3½ per cent.

There was also an easier undertone in time money, 60 and 90 day paper being quoted at 5½ per cent to 5½ per cent, as against a uniform rate of 5½ per cent in the previous week. The longer maturities up to six months were quoted at 5½ flat as against a range of 5½ per cent to 5½ per cent in the previous week. The market in general continued quiet with few, if any, important transactions recorded. Prime commercial rates remained unchanged at 5½ per cent to 5½ per cent.

The Federal Reserve Bank statement as of Oct. 19 showed that both the Federal Reserve System and the New York institution have strengthened their positions materially, each showing large gains in gold reserves and contractions in bill holdings. The Federal Reserve System showed a total reserve ratio of 70.3 per cent as compared with 68.5 per cent the week before. Total gold reserves stood at \$2,772,721,000, an increase of \$43,799,000 over the figure for the previous week, and the high point for the year, the low having been \$2,080,262,000 on Jan. 7.

Federal Reserve notes in circulation decreased \$35,449,000, the actual amount in circulation as of Oct. 19 being \$2,440,862,000, the low point for the year. Total bills on hand showed a decrease of \$79,723,000 from the previous week, while bills discounted secured by United States obligations amounted on Oct. 19 to \$459,671,000, the low point for the year. Total earning assets at \$1,577,900,000 showed a decrease of \$102,303,000, a record low for the year, and a decrease of 53 per cent below the total reported about a year ago.

The total gold reserves of the New York Federal Reserve Bank increased \$74,735,181 to \$1,033,149,181. Total earning assets decreased \$89,000,000, and the total of bill holdings declined to \$272,619,000, a contraction of \$71,347,000.

### ARGENTINE OUTLOOK BRIGHTENS

BUENOS AIRES, ARGENTINA, Sept. 28 (By Mail)—The American Chamber of Commerce here feels that a great improvement has taken place in general business conditions during the last two months. In discussing the present situation, M. T. Meadows, manager of the Chamber, said: "Frankly, I feel that the corner has now been turned and at last we are in a position to expect a slow but steady return to satisfactory business conditions."

## MEN OF THE INDUSTRY

George Drake Smith has been appointed general sales manager for trucks by the Steinmetz Electric Motor Car Corp. of Baltimore. To accept this position Smith has resigned as vice-president, director and general sales manager of the Winther Motor Truck Co., Kenosha, Wis. For several years he was with the General Vehicle Co., which manufactured electric trucks, and later was with the Edison Storage Battery Co. at Orange, N. J., as manager of its electric vehicle department. He has an acquaintance which extends from coast to coast. It is expected that the Steinmetz truck, after two or three years of development, will be in production about Dec. 1. It is said to be lighter than any similar truck on the market and to have unusually high speed, as well as simple design.

Richard H. Magoon has joined the sales department of the Leach Biltwell Motor Car Co. of Los Angeles as assistant to Charles Hagenios, sales manager. T. A. Heindol, for a number of years assistant manager and purchasing agent of the Miller Engine & Foundry Works of Los Angeles, has joined the Leach organization in the capacity of assistant purchasing agent. The Miller plant and organization was recently taken over by the Leach company. Forrest P. Richardson, a director of the company and purchasing agent, recently was named assistant general manager of the company, but will continue to head the purchasing department.

Ralph D. Mock, vice-president and former comptroller of the Hydraulic Steel Co., Cleveland, has become vice-president associated with sales. Mock, prior to his nine years of service as finance executive for the company, had a broad experience in sales work. Harry W. Kranz, former superintendent of the Cleveland Welding & Mfg. Co. of the Hydraulic company, has been appointed manager of the welding plant. Charles S. Holden, formerly in the sales department of the Cleveland company, has been named sales manager of the welding plant.

Brock Mathewson, one of the veterans of the automotive industry, has taken up his duties as vice-president and sales manager of the Reynolds Spring Co. at Jackson, Mich. He has abandoned his original plan of building up a manufacturers' representative service in Detroit. Mathewson came into the automotive industry back in the bicycle days. During the war he was connected with the automotive division of the Savage Arms Co. in an executive capacity.

F. E. Badger, for the past ten months a member of the sales-engineering staff of the Detroit Steel Products Co., manufacturer of Detroit Springs, has been appointed sales manager of the chassis spring division of that company. For eight years Badger was plant manager of the Standard Parts spring plant, at Flint. Following the war he was general manager of the spring plant at Canton, Ohio.

E. E. McCleish, formerly director of publicity and publications for the Willys-Overland Co., who recently built up an advertising and sales copy business of his own, has combined his business with that of the United States Advertising Corp., of which Ward Canaday is president. McCleish came to Toledo from the Curtiss Aeroplane and Motor Corp. in Buffalo.

Richard B. Mann has been appointed general manager of the Packard Motor Car Co. of Missouri, with headquarters at St. Louis. Alvan Macauley is president, suc-

ceeding P. S. Russel who resigned; and Dr. H. H. Hills is vice president. Mann has been connected with the Packard in Newark and New York.

E. W. Hlatt has joined the organization of the A. B. B. Sheet Metal Works, Milwaukee, in the capacity of factory manager. Hlatt was formerly with the Maxwell-Briscoe Co., serving as superintendent in the body and steel metal department. More recently he was connected with the Dort Motor Car Co. in a similar capacity.

N. T. Norton, Jr., who recently resigned as chief engineer of the Motor Transport Division of the Quartermaster Corps, U. S. A., is now designing a new line of truck axles to be marketed by a company that is now being formed. Norton's offices are in the Monadnock Building, Chicago.

Ben G. Campbell has been named southwest sales manager of the Anderson Motor Co. of Rockhill, S. C. For eight years Campbell was connected with General Motors. Since 1919 he has been analyzing trade territories west of the Mississippi for a number of concerns in the industry.

Hans Renold of Birmingham, England, who is one of the large chain manufacturers in that country, is now calling on bicycle, motorcycle and truck builders in the United States. It is understood he contemplates starting an American factory to make roller chains.

Harry Tipper, business manager of AUTOMOTIVE INDUSTRIES, will address the students of the engineering classes of Purdue University at Lafayette, Ind., the afternoon of Oct. 31. He will speak to the Lafayette Rotary Club earlier in the afternoon.

M. B. Loomis, advertising manager of the Sparks-Withington Co., Jackson, has returned from a three weeks' trip covering eastern jobbers. He finds business good, with jobbers clearing their stocks and buyers buying.

LeRoy Kramer has been elected president of the Rochester Motors Corp., Rochester, N. Y., and C. J. Symington, president of the T. H. Symington Co., has been named chairman of the board of the Rochester corporation.

Allan C. Chambers, formerly sales manager of the Russel Motor Axle Co., Detroit, has been appointed sales manager of the Hartford Automotive Parts Co., Hartford, Conn., with headquarters, for the present, in Detroit.

William N. Freeman, for some time secretary of the Flisk Rubber Co., Chicopee Falls, Mass., has been made assistant sales manager of the company's Federal division with headquarters in Cudahy, Ohio.

C. A. Thurston, export manager for Earl Motors, Inc., has sailed for England, where he will visit the Olympia Show. He also plans a trip to various countries of the Continent.

O. W. Williams, for the last four years in charge of material and costs with the United States Motor Truck Co., has been appointed to the position of purchasing agent with the company.

Wilson S. Porter has returned to Chicago as manager of the Locomobile Co.'s branch, succeeding H. S. Norton. Porter recently was Boston branch manager.

C. J. Morrison, for the past two and a half years executive assistant to the president of the Atlas Tack Corp., has resigned.

John T. Turcott has been appointed general superintendent of Stevens-Duryea, Inc., Chicopee Falls, Mass.

W. H. Herbert has been appointed sales manager of the Denby Motor Truck Co., Detroit.

## FINANCIAL NOTES

Durant Motor Car Co. of Canada, Ltd., soon will offer to the public \$1,250,000 of \$10 par value stock. W. C. Durant and his associates already have taken \$750,000 of the \$2,000,000 authorized stock. The shares will be convertible in Aug., 1924, into capital stock of the parent company on a basis of \$30 for the United States stock and par for the Canadian. It is expected that production in the Toronto factory will commence by the end of the year and that the first cars will be marketed in the Dominion about March 1.

Russel Motor Car Co., Toronto, profits for the year ended July 31 were \$158,124 compared with \$339,453 the previous year. Business was uneven among the various subsidiaries and on the whole the company experienced the uncertainties of present conditions. The balance sheet shows a reduction in bankers' advances from \$500,000 to \$120,000. Accounts and bills payable have also been reduced, standing now at \$89,947 against \$416,025 a year ago.

Stewart-Warner Speedometer Corp., net profits for the quarter ended Sept. 30, before provision for Federal taxes, were \$552,894, against \$801,278 a year ago, and for nine months totaled \$755,967, against \$2,271,426 in the corresponding period of 1920. Inventories now have all been marked down to market. The corporation declared the regular quarterly dividend of 50 cents a share, payable Nov. 15 to stock of record Oct. 31.

Stanwood Rubber Co.'s plant at Elizabeth, N. J., has been sold in Chancery Court at Newark for \$360,000, thus terminating the receivership. The reorganization plan calls for issues of \$175,000 8% pfd. stock, \$151,000 8% 2nd pfd., 500,000 shares no-par common. Creditors' \$600,000 claims will be paid 50% in non-interest bearing debentures and 50% in common stock of \$2 par.

Durant Motor Co. of Indiana, with a capital of \$3,000,000, has been incorporated at Indianapolis. It is to manufacture the Durant Six in Muncie, in the Sheridan plant, purchased from the General Motors Corp. three months ago. The company will have 800 men employed by Jan. 1 and ultimately expects 4,000 on its payroll.

Sinclair Motors Corp., Springfield, Mass., will pay a dividend of 3 per cent to all creditors through an order by Referee in Bankruptcy Charles W. Bosworth. This is the first dividend declared since the company was adjudicated a bankrupt.

Ford Motor Co. of Canada will pay a cash dividend of 15 per cent on Nov. 15. The disbursement will total \$1,050,000 and will be the second cash dividend of that amount paid by the company in the last six months.

Briscoe Motors Corp. of Jackson, Mich., has filed an amendment to its charter, which was issued in Delaware, changing its name to Earl Motors, Inc., and increasing its capital from \$21,500,000 to \$41,500,000.

Lee Rubber & Tire Co. has declared its regular quarterly 50 cent dividend, payable Dec. 1 to stock of record Nov. 15.

## PORTUGAL HONORS CASE

RACINE, WIS., Oct. 24—Information has been received by the J. I. Case Plow Works Co. that the Portuguese Farmers' Association has bestowed its gold medal and first honor prize for the best agricultural machinery group at the Lisbon exhibition upon Monteiro Gomes Limitada, handling the distribution of Case implements in Portugal and Spain.

## INDUSTRIAL NOTES

New England Tire & Rubber Co., South Holyoke, will start production this week in its new plant, and expects to attain an output of 300 pneumatic and cord tires a day within two months and have 200 employees at work. Capacity of the factory is 1,000 tires and 1,500 tubes daily. Up to the present the company has had its product made under contract by a Brooklyn concern, and has produced \$1,000,000 worth of tires in the last year. A factory branch has been opened in Washington, in addition to the branches previously established in New York, Newark and Boston.

United Automobile Body Co. will begin production early in November in the plant at Danville, Ill., formerly occupied by the Moore Motor Vehicle Co. The general offices will be opened with the transfer to that city of R. M. Hawn, chief engineer; E. W. Windsor, sales production manager; and William R. House, sales manager. It is the intention of the company to divert all production to the main plants at Danville and Springboro, this policy decreasing the overhead and supervisory expense. Later, if conditions warrant, the other branches may be given more activity.

Perfection Tire & Rubber Co. stockholders attended a mass meeting at Peoria, Ill., to allow President Preston E. Roberts and General Manager James Rosenthal an opportunity to give first hand information concerning the activities of the company. It was stated that \$2,000,000 of Peoria money, invested in the company, was secure, and that the plant at Fort Madison, Iowa, is operating upon full time. Following the statements confidence was expressed in the policy and methods of the executives.

Mirrorlike Mfg. Co., is moving to its new plant, Queensboro Boulevard and Buckley street, Long Island City, which has been especially constructed for the manufacture of the company's products. The plant will permit of a ten-fold increase in business. Additional land will allow further facilities as needed. The company has added a special department for the manufacture of greases, soaps, motor oils, etc.

The Morand Cushion Wheel Co. has bought a 20-acre site in Chicago upon which it expects, as soon as local building conditions permit, to build a new factory to cost in the neighborhood of \$1,000,000. The new plant will be modern and complete in every respect, embracing rubber making, woodworking and foundry departments. Business with this company is reported good and the future very bright.

Glenwood Motor Co. has made arrangements to locate its main plant at Findlay, Ohio. It is a Cleveland concern and was organized three years ago. Work on a new factory building on a 25-acre site in North Findlay will start soon. The Greater Findlay Corp., capitalized at \$100,000, has been formed by local capital to provide housing accommodations for the men employed by the motors corporation.

El Dorado Motor Device Co., which has been incorporated with \$100,000 capital stock, will maintain a factory at El Dorado, Ark., for manufacturing anti-kicking devices, and attachments for motor and gasoline engines. J. G. Pratt is the president; Ed. Combs, vice-president; O. A. Heath, secretary, and G. M. LeCroy, treasurer.

Commercial Car Co., of Detroit, has purchased the plant and properties at Knoxville, Tenn., of the Southern Valve & Gear Co., for

conversion into a truck manufacturing plant. The deal was consummated by F. E. Fitzgerald of Detroit general sales manager for the company.

Columbia Tire & Supply Co., Lafayette, Ind., has changed its name to the Columbia Automobile Supply Co. and has removed to larger and more complete quarters. The changes do not involve any alteration in the personnel of stockholders or management.

New Britain Machine Co., New Britain, Conn., will shortly begin the production of motor cycles, according to a statement by company officials. Nothing definite is said as to the type that will be manufactured. Business in the tractor department is quiet.

Porter Rubber Co.'s plant at Salem, Ohio, has been sold to L. W. Hicks, Pittsburgh, for \$73,000, the sale including the entire equipment. The plant was sold to satisfy a judgment for \$85,000 entered in the Common Pleas court of that city in favor of Hicks.

Kelly-Springfield Motor Truck Co. force at Springfield, Ohio, is being gradually increased with skilled men. Orders are coming in from dealers and the outlook is growing more encouraging. James L. Geddes, chairman of the board of directors, states.

S. F. Bowser & Co., manufacturer of oil tanks and pumps, which has been operating on part time during the summer will resume on full time Nov. 1. A wage cut amounting to from 10 to 15 per cent will be put into force.

Robert H. Hassler Co., Inc., of Indianapolis is planning the construction of a two-story brick and steel building which will be used as an addition to its plant for the manufacture of automobile shock absorbers for larger cars.

Easthampton Cork Co., Easthampton, Mass., has opened a shop for the manufacture of cork sheets for automobile gaskets, starting with contracts that assure the operation of the plant for a year and a half.

Fisk Rubber Co., Chicopee Falls, Mass., has made a reduction of 100 in the night shift of its tube department for the reason that tube production has been running ahead of tire work.

Lightning Chain Auto Wheel Corp. has purchased property in Rochester and will begin manufacturing the Roblin demountable rim retaining device by Nov. 1.

Paragon Motor Co., Cumberland, Md., has awarded a general contract for the superstructure of its new plant. Foundations for the plant have already been laid.

The Buda Co. announces that the office of the eastern sales manager has been removed from 33 West 42nd street, New York to 30 Church street.

Non-Explosive Appliance Co., Fort Wayne, has created a sales and advertising department, which will be headed by W. H. Minchin.

## JOHN BOYD DUNLOP DIES

NEW YORK, Oct. 25.—A dispatch from Dublin says that John Boyd Dunlop, known as the inventor of the pneumatic tire, died there yesterday at the age of 81 years. His invention, first introduced in 1888, made bicycling popular and was a forerunner of passenger automobilism. Dunlop, who was a veterinary surgeon, was led to develop the pneumatic tire through his devotion to his invalid mother who was compelled to use a wheeled chair. He hit upon the use of inflated rubber tubes around the wheels of his mother's chair to make it more comfortable for her.

## METAL MARKETS

In view of the U. S. Steel Corporation's loudly proclaimed \$7 cut in its rail price, those steel producers who are constantly essaying price advances would at first blush seem to be hopelessly out of step. The facts in the case, however, serve to modify this impression. The cut in steel rail prices was one of those brilliant moves which the master hand that guides the Corporation's destinies can always be relied upon to make when opportunity offers to improve the Corporation's relations with the public.

Choosing the psychological moment when labor's balking at unavoidable wage cuts threatened to dislocate the nation's business, Judge Gary resorted to this step so as to impress upon the American people the readiness of the country's largest corporation to "take its medicine" with a smile. Market-wise, however, the announcement was as devoid of significance as it was important from a public affairs point of view.

Rails have always been considered apart from other steel products and for upward of a dozen years before the war has sold at the quasi-stabilized price of \$28. When the downward revision of steel prices began last December, it was commonly understood that the reason no change was announced in the price of rails from the \$47 quotation, which had been inherited from the Industrial Board's price schedule, was that the railroads were in no position then to place orders for rails and that readjustment of the rail price could well wait until the carriers were once more financially on their feet.

The \$47 rail price was generally recognized as an unmeaning nominal figure, so that its lowering by \$7 must not be interpreted as signifying even in the remotest manner a tendency on the part of the leading producing interest to put into effect other price reductions. In fact, there is at the present time in evidence a total absence of the determined leadership that characterized the steel market in its heyday. The largest producing interests appear to have their misgivings as to the possibility of maintaining any sort of price policy and seem perfectly willing to have some of the more aggressive "independents" try their luck with advances as a means of bringing out orders at the old prices and "sugaring" averages.

Pig Iron.—Buying and prices are tapering off, many consumers holding off in the expectation of early cuts in freight rates. Steel mills are again sellers of surplus production of pig.

Steel.—Non-integrated sheet mills have been buying modest tonnages of sheet bars for which they have had to pay higher prices. The sheet market is irregular. Passenger car builders are buying odd tonnages of cold-drawn and strip steel to piece out what stocks they have on hand so as to maintain their production schedules over the year's remaining two months. Bolts and nuts are moving in a routine way only.

Aluminum.—As intimated in previous market reports, German interests have advanced their prices on sheets to the extent of 2 cents per lb., regular selling agents now quoting 30¢ @ 31¢ base on flats and coils and 33¢ on circles. No ingots are offered by the Germans. The Aluminum Co. of America has reduced its price for sheets about 4¢ a pound, bringing flat sheets 18 gauge and heavier to 35¢ and coil to 30¢.

Copper.—The flurry in the copper market has apparently spent itself and bargains are once more offered and spurned.

# Calendar

## SHOWS

- Nov. 14-19—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association, Fourth Regiment Armory.
- Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.
- January—Chicago, Automobile Salon, Hotel Drake.
- Jan. 7-13—New York, National Automobile Show, Madison Central Palace, Auspices of N.A.C.C.
- Jan. 28-Feb. 4—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.
- Feb. 6 to 11—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.
- Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

- Nov. 4-12—Car Show. Nov. 28-Dec. 3—Motorcycle Show.
- Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.
- Nov. 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.
- Nov. 12-27—Buenos Aires, Annual Motor Show, La Pabellon de las Sosas, Automovil Club Argentino.
- Nov. 26-Dec. 3—Shanghai, China, Automobile Show.
- March, 1922—Santiago, Chili, Annual Automobile Show.
- May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibits in connection with the Brazilian Centenary Association Automobilista Brasileira.

## CONVENTIONS

- Oct. 28—New York, American Iron and Steel Institute.
- Nov. 1-4—New York, Industrial Relations Association of America.
- Nov. 3—Indianapolis, Meeting of Friction Drive Engineering Society.
- Nov. 14-19—Chicago, Annual Meeting and Business Exhibit of Automotive Equipment Association.
- Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.
- Nov. 21-23—Atlanta, Third Annual Convention of American Farm Bureau Federation.

Dec. 6-8—Chicago, Second Annual Meeting of American Petroleum Institute.

Dec. 10—New York, American Institute of Mining and Metallurgical Engineers.

Dec. 20—Philadelphia, American Society of Mechanical Engineers.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

Jan. 17-20, 1922—Chicago, American Road Builders Association.

Sept. 18-23, 1922—Rome, Italy, Second Annual Meeting of the International Chamber of Commerce.

## S. A. E. MEETINGS

Detroit, Nov. 18, Dec. 23, Feb. 24, March 24, April 28, May 26.

New York, Jan. 11-14, 1922—Annual Meeting.

Chicago, Feb. 1

Minneapolis, Feb. 8—Tractor Meeting.

## Ready to Produce New Maxwell Series

### Frame Is Stronger and Redesigned —4-Cylinder Engine Little Changed

DETROIT, Oct. 24—The Maxwell Motor Car Co. is about to enter production on its new series. The changes are principally in the larger and more substantial bodies and a stronger and completely redesigned frame. The same four-cylinder engine is employed with only minor changes. In exterior appearance, the car has been substantially improved. The radiator is higher and larger.

The bodies have been refined from one end to the other and mechanical improvements include the adoption of Alemite chassis lubrication, easier clutch and brake action, longer springs, new mounting of starting motor on the bell housing and new type of tire carrier.

Probably the outstanding feature of the new series is the superior trim and fitting of the new bodies. Real leather upholstery is used in the open cars and special broadcloth in the closed. The seat and back cushion springs are greatly improved. All doors are provided with pockets and the side curtains open with the doors on solid rods and supports. There is a plate glass window in the rear curtain of the open cars and the equipment now includes the drum type of headlamp, motor-driven horn, better set of tools and better body hardware. The new 31 x 4 cord tire is employed which helps to make the car lower. Prices have not yet been fixed.

## Wills-Sainte Claire Line Gets Sedan Addition

MARYSVILLE, MICH., Oct. 24—C. H. Wills & Co. is now making deliveries on

a sedan which is the latest addition to the Wills-Sainte Claire cars. There are two auxiliary seats that fold flush with the back seat so that the sedan accommodates seven. The model has four doors. A glass partition between the front and rear compartments can be furnished if desired.

The interior woodwork is of walnut and the hardware of special design with satin silver finish. The windows are crank operated and are provided with silk shades. The fittings include a vanity case containing mirror, memorandum books and silver topped bottles, double ash tray and match holder, corner reading lights, dome lights and robe rail.

## Cooler Weather Helps Philadelphia Business

PHILADELPHIA, Oct. 24—According to Charles C. Bulkeley, executive secretary of the Philadelphia Automobile Trade Association, the automobile industry has improved notably since the cooler weather set in. He expresses the opinion that sales will steadily increase and that the automobile show, to be held in January, will begin one of the best years the industry has experienced.

Automobile dealers here generally state that business has improved decidedly since Oct. 1. Increases over September sales are estimated at from 10 to 40 per cent, by a majority of the large distributors here.

## CITIZENS AID WAYNE TIRE

ORRVILLE, OHIO, Oct. 24—Citizens of Orrville have pledged \$50,000 towards a fund of \$75,000 asked by the Wayne Tire & Rubber Co. to make necessary improvements in its plant. The company is said to have liquidated its indebtedness and proposes to increase the capacity of its factory to keep up with demand which is now running in excess of production, although the plant is being operated 24 hours a day.

## Britain Increases Imports in Tires

### Receipts and Shipments of Automobiles Show Falling Off During September

LONDON, Oct. 16 (By Mail)—September is a comparatively slack month for the British automobile trade, and this year it has well maintained the tradition. Compared with August there was a drop of \$427,790 in imports of vehicles and chassis and of \$47,950 in parts, but a most remarkable increase of \$941,315 in tires.

British automobile exports showed a drop of \$38,420 for vehicles and chassis; of \$20,865 for parts, and an increase of \$192,460 for tires, compared with August's values. Thus, although the trade has been quiet, it showed a good increase under both heads, imports and exports being respectively \$465,575 on imports and \$122,175 for British exports.

Considering the imports, the number of cars was 565 (1264), trucks 48 (804), and chassis 310 (1231), and motorcycles and tricar 1557 (105)—the figures in brackets being the corresponding month's figures in 1920. The value of imported vehicle parts and components was \$661,815 (\$6,982,715) and of motorcycle and tricar parts \$75,215 (\$82,245), and tires (value) \$2,924,565 (\$2,909,730).

British export of cars numbered 29 to British India (103), 6 to New Zealand (58), and 80 to other countries (304)—total 115 (465); trucks to British India 4 (32), to New Zealand none (7), and to other countries 27 (72)—total 31 (111); chassis to British South Africa none (1), to other countries 47 (452)—total 47 (453); motorcycles and tricars (destination not scheduled) 425 (2815). Parts valued \$457,345 (\$883,835), motorcycle and tricar parts \$94,205 (\$317,649), and tires \$826,735 (\$257,430).

# **Champion** Dependable Spark Plugs

Establishing the Southern speed record, a Lark model Lexington Standard car equipped with Champion Dependable Spark Plugs, recently defeated the Dixie Flyer from Atlanta, Ga., to Jacksonville, Fla.—a distance of 374.6 miles.

**Champion Spark Plug Co.**  
Toledo, Ohio

## Another Victory

### Pike's Peak Hill Climb

On Labor Day, Sept. 5th, a Lexington Special No. 7 was piloted to victory in the event for cars of 183 to 300 cubic inches displacement.

"We attribute no small share of our success to the fact that your Champion Spark Plugs were used, and are very pleased indeed to most heartily endorse same, as our exhaustive dynamometer tests have proven, to our satisfaction, that there is no better plug on the market."

**Lexington Motor Co.**

Champion two piece construction with 3450 insulators and patented gaskets again prove their dependability.

# WALTHAM SPEEDOMETERS AND AUTOMOBILE CLOCKS

*The only  
Air-Friction  
Speedometer  
in the world*

**A**IR-FRICTION? Just what is "Air-Friction"? It is a new principle for use in speedometers developed and perfected by the Waltham Watch Company.

*Explained briefly* — The dial indicator is hung on a shaft in a jewel-bearing and driven by the friction of air generated within the instrument according to the speed of the car. The dial indicates every speed with absolute and instantaneous accuracy.

The safety and satisfaction of the car owner are often seriously affected by the irregularity and unreliability of speed-recording.

A Waltham Speedometer avoids all of these disadvantages. It records every variety of speed instantly and accurately. It is not affected by climatic or temperature changes.

More and more of the leading automobile manufacturers in this country are specifying Waltham Speedometers as standard equipment for their cars. Among such cars are the Cunningham, Daniels, Fergus, Lafayette, Leach-Biltwell, Lincoln, Packard, Pierce-Arrow, Renault, Rolls-Royce, Stevens-Duryea, Wills-Sainte Claire, and others.

Why not make it a special point to visit the agencies representing any of these cars which are equipped with this truly wonderful Speedometer. A demonstration will prove to you the instant accuracy of the Waltham Speedometer.

## The Meaning of Service to the Automotive Industry

Service means taking care of the owner; keeping him satisfied. Service and parts will ultimately be handled by whatever agency can do the job most economically. Service industry growing.

By Clyde Jennings\*

**I**T seems rather difficult to get all persons concerned to realize exactly what service means to the automotive industry. Two definitions of service that are very far from the correct one appear to be accepted in many quarters. These definitions, stripped of camouflaging words, are:

1. An opportunity to make money on the person who bought the vehicle.
2. Another name under which the vehicle owner forces you to give him something.

The fact is, that the person who holds either of these definitions to be even approximately correct, has not caught even a part of the spirit that must be put into the service department of the industry.

A proper definition of service does not appear to have been written. Some of the components of service are definitely known. A few of them are:

1. Service must be to the industry what the shoe repairer is to the shoe manufacturer. As long as repairs are more profitable to the owner than new vehicles, they must be supplied at a reasonable price and in workmanlike manner.
2. Service must become a perfectly legitimate business and after the 90-day guarantee period service work must be self-supporting.

3. Service business must necessarily grow with the number of cars in use, which will be at a greater rate than the increase in number and financial importance of the vehicle manufacturing industry. This follows as certainly as the percentage of sales lessens in proportion to the number of cars in use.

4. Efforts to improve service must be to the improvement of all service, for no one manufacturer can ever hope to have enough service stations to care for his vehicles, and they must, if the owner uses his car to the best advantage, at times be at the mercy of the independent service man. It is best that this service man know as much as possible about this car, so that he can send the owner on his way in a fairly cheerful frame of mind.

Recently there has been a rather energetic discussion as to who should distribute the parts to be used for service—the maker of these parts or the assembler of the truck. There are various reasons advanced pro and con—but in the main, the chief reason that would appear to be involved has been little mentioned. From a merchandising standpoint there is but one question to be asked—

Who can distribute these parts to the best satisfaction of the vehicle owner?

\*Managing Editor, *Motor Age*.

There are some interesting angles to this discussion. Most men of to-day can remember—if they can't, their fathers can—when the stove repair question was a serious one in the household. Stove manufacturers prided themselves on making a stove that was unlike any other stove in every material part. The lids, bolts and what-not of one stove could not be used for another. If you burned out the lid of a stove, and the local merchant had quit handling that particular stove, the family purse had to be drawn upon for the extraordinary expense of sending to the factory for another. Transportation was as poor in those days as in 1920 and perhaps the stove was out of commission for days.

### Parts Standardization

Then some one had a bright idea. It was this—the province and business of the stove manufacturer was chiefly to manufacture and sell to the people stoves that would cook the food, keep them warm for the longest time possible. Also to best perform these functions, it was quite necessary that repairs be made as quickly and efficiently as possible. So a good many parts of the stove were standardized. Bolts, plates and other parts became of similar size. The parts business, which had been a source of trouble, was forgotten and “stove parts dealers” appeared in many cities. These men advertise that they have parts for any stove, and usually they have.

The result is that the gossip among people as to the makes of stoves and service has ceased and failures are no longer the cause of people advising their neighbors not to buy a certain stove because they cannot get repair parts. The stove business is more prosperous than ever before.

Just think what would be the result if Mr. Douglas would announce that no pair of Douglas shoes could be repaired unless the leather was bought from his parts department?

Service is, and must be, considered an important function in selling. How many repeat sales will the car manufacturer make if he treats his owners only as a source of profit for parts and repairs? A study of the history of the farm implement business in this regard would be illuminative. The companies that have survived are those which tried to supply service. It has been largely a case of the survival of the fittest.

It is well worth considering how long the manufacturing industry can control the service industry, or whether the manufacturing industry has not created a Frankenstein industry in service. The number of service shops in the United States is estimated all the way from 21,000 to 45,000, according to the definition given of the term “service shop.” For the purposes of this article, however, suppose there are 33,000 such shops. The most conservative estimate of the average number of employees in these shops is five. From five the figure ranges upward to seven and even more. Let us put the figure at a compromise and say that there are six in each shop. That seems like rather a small average, when you stop to consider the number of very large shops. With an average of six men to each service shop, we have a total of almost 200,000 men engaged in the servicing of automotive vehicles. As we understand these figures, this does not include the men in the private shops, which would include the shops conducted by a

number of large fleet owners, so the number must run even higher. It is to be regretted that there is not at hand a definite statement of the number of men engaged in this particular work.

The Census Bureau in its report on manufacturing activities in 1919 stated that there were 15,486 automobile repair shops and that the value of the products was \$2,387,833,000. These figures compare with 3273 shops in 1914, with a product value of \$503,230,000. A request to the bureau for a definition of an automobile repair shop brought this reply:

“The census of manufactures includes automobile shops only when they use power-driven machinery and partake of the nature of a machine shop. An establishment storing, washing and making minor repairs on a car is not included. The shop must be so equipped as to be capable of manufacturing new parts if necessary or it does not come within the scope of the manufacturing census, which is confined to factories. If a concern stores and sells cars and also maintains a repair department of sufficient importance to come within the census, a segregated report is required and only the statistics for the repair department are included.”

The National Automobile Chamber of Commerce has estimated that there are 300,000 men engaged in the manufacture of automotive vehicles. This estimate, as we take it, is one made when the industry was running at a rather high rate, so according to the present figures the industries are about on par.

The future is vastly different. According to the registration figures, the service man was called upon to handle an increase of 30 vehicles dur-

ing the year of 1920. There will be another increase in 1921. It is the belief of all those engaged in the automotive industry that the number of vehicles registered from year to year will grow constantly for a good many years. In fact, the only possible limit put upon registration is the introduction of a better vehicle than the automotive vehicle. It is also a fact that the employment in the manufacturing end of the industry will not be as heavy in 1921 as it was in 1920, so it will probably fall below the 300,000 point. During the year it would appear that the service industry is somewhat at least as large as to number of men employed as the manufacturing industry.

A rather unusual question enters here. It seems that vehicle manufacturers want to draw a line through the service business, and the place of this line is not at all well defined. The manufacturers have permitted in recent years certain of the parts makers to establish chains of service shops. Battery and bearing makers are notable examples of the direct service. Vehicle manufacturers, as a rule, have been quite glad to get rid of this part of the service and have advised the owners of their vehicles to patronize the special service plants for these repairs. A man needs be quite expert in definitions to tell on which side of the line service should come.

Present service troubles are largely the result of human weaknesses and a lack of fundamental organization. Often where the organization has been started with good intentions, the human weaknesses have swamped the organization. It is natural for the ma-

This cartoon was drawn as a joke—Shall the industry make it a fact?

(Reprinted from The World)

majority of men to attempt the short road to wealth. Many men think this road is along the route of getting all you can and getting it quick. So many service people have not been able to see that a well conducted, day in and day out business is better than one where you charge all that the traffic will bear and do just as little as possible.

This theory has been the mainstay of the maker of unreliable parts. He is able to turn out a part that will serve for the time being. Neither he nor the service man to whom he sells is much concerned as to how long it will last. Perhaps the service man may have a good enough idea of business to want to do a good job, but a smooth salesman from the unreliable parts maker has convinced him that this cheaper part will do the work just as well. Perhaps the sample was good, but the question is as to the run of the factory. A service man may be honest and still not have the facilities for judging the parts shipped to him. If he has not these facilities he must deal only with reliable firms. Some independent parts manufacturers have established themselves as makers of reliable parts and frequently they supply parts of slightly different design or material from the original that supply a choice in making changes or repairs in the vehicles. It can be said, in truth, that some car makers have at times been entirely unable to supply parts for their own cars and these cars have been kept on the road by independent parts makers and no objection has been found to the parts.

An engine maker not long ago received a complaint from a service man (who enjoys an excellent reputation) that a lot of bearings he had bought were not giving proper performance. The engine maker had the bearings shipped to his factory. The factory men saw at once that these bearings had never been in their stock and it later developed that they had been shipped to the service man by the truck assembler. The assembler bought them (apparently in good faith) thinking they were entirely satisfactory.

A long time is required to build up an industry of the size of the automotive service industry to the point where it will function with reasonable certainty. A new industry always attracts adventurers and promoters. There was a time when the service industry was made up almost wholly of this type of men. Fortunately this day has gone. The personnel of the service shops to-day is of a much higher grade than a few years ago. There are many men in the service business who see in it an opportunity for a just and fair business. They look to the future confidently and their hope is to establish a business that can be handed from father to son. The same can be said of manufacturers of independent parts.

It is on such men as these that the future of the service business depends. There is, unfortunately for quick

action, much in this new industry that depends upon co-operation with factories and with engineering. Where these men are directly connected with factories they get co-operation, but in the main they do not get co-operation unless they are "authorized," and in most cases that means connected with the selling of the vehicle.

One of the great needs of the service industry to-day is the elimination of secrecy and mystery. In some cases this secrecy and mystery has been due to manufacturing imperfections. As time goes on, there will be less of this in the factories, and the service man will get a better understanding of the product on which he is working.

The importance of service is coming to be recognized to an increasing extent in design work. The car and truck designer in many plants consults intimately with the factory service manager in working out new models. In certain instances, factory service managers have worked out methods of keeping in touch with owners and service stations, so that future designs can have immediate benefit from service experience.

The service factor is entering into design, also, because it is recognized that a larger percentage of buyers every year are replacement buyers. The man who owns a car for the first time may not consider seriously the service phase of car ownership, but the man who is buying his second or third car will look into that phase carefully. The manufacturer is responsible for keeping the owner satisfied. When the service organization functions efficiently, service becomes a real help to future sales.

The manufacturer is often in a position to investigate methods and equipment in a way not possible for the individual service station. Some manufacturers, for example, have gone so far as to test out and investigate service station machinery and to recommend certain types of tools for use in their service stations.

Standardization is making for great progress in the service industry. It will go even further. To-day qualities of drop forgings and similar articles that go into practically all cars are carried by supply houses, such as hardware supply stores.

More and more men each year are gaining an understanding of the new transportation vehicle, for it is new despite the seeming public familiarity with it. The changes in manufacture have been rapid. No one man could keep all of these changes in mind. The mechanic who is a competent worker on one make of car is better equipped to work on all cars than was the man with so restricted an experience a few years ago.

Service is not hopeless, by any means. It needs more time, more patience and more conscientious effort and less selfishness.

# New Duesenberg Reflects Experience Gained with Racing Cars

Striking engineering features characterize the latest product. An eight-in-line engine, four-wheel brakes, overhead camshaft, and tubular connecting rods are included in design. High pressure oiling is employed. Drive shaft and front axle are tubular. Semi-elliptic springs used.

By J. Edward Schipper

**I**NCORPORATING such features as an eight-in-line engine, hydraulically operated four-wheel brakes, overhead camshaft, tubular connecting rods and a weight of only 3200 lb. in spite of a wheelbase length of 134 in., the new Duesenberg presents some very interesting engineering features. This car is one of the most direct interpretations of racing experience which has ever been offered the public. Its engine is identical in many respects with the 183 cu. in. engine of the Duesenberg racer which recently won the French Grand Prix race. With a bore of  $2\frac{7}{8}$  in. and a stroke of 5 in., it has a displacement of 260 cu. in. and develops from 90 to 100 hp. An output of 1 hp. per 2.6 cu. in. of piston displacement with a compression of 80 lb. per square inch gage gives a good idea of the characteristics of the engine. The upper half of the crankcase and the cylinder block containing the eight barrels are cast as a unit. The cylinder head is removable and incorporates the overhead camshaft and rocker arms. The valve and spring mechanism are inclosed by a detachable cover plate and the lower half of the crankcase and the oil pan are a unit aluminum casting, removable while the engine is in the frame.

The pistons are magnalite, although cast iron will be supplied if desired. They are of flat-top design,  $3\frac{1}{8}$  in. in length, with three  $\frac{1}{8}$ -in. rings. The tubular connecting rods are  $9\frac{3}{4}$  in. in length, machined all over and equipped with annular cooling ribs at the lower end. The piston pin is held in the upper end of the connecting rod by a lock screw, the

bearing being held in the piston.

Three main bearings support the one-piece crankshaft. The crankshaft diameter is  $2\frac{3}{8}$  in. at all main bearings, and the bearing lengths are  $2\frac{1}{2}$ ,  $2\frac{1}{2}$  and 3 in., front, center and rear. The lower connecting rod bearings are all 2 in. by  $1\frac{7}{8}$  in. It has been found that the use of a smaller diameter at the end of the throw than at the main bearing is a material factor in assisting balance of the crankshaft. Spiral bevel gears and a vertical shaft are used for driving the one-piece, hollow camshaft which is mounted on five bearings. There are two valves per cylinder, each actuated by a forged alloy steel rocker arm, and two concentric springs. The valves open downward directly into the spherical combustion chamber, which is polished to prevent carbon collection. The vertical drive shaft is made in two pieces so that the head can be removed and replaced without changing the valve timing, the driving lug on the vertical shaft being offset so that the head can be replaced in only one way.

High-pressure oiling is employed, the oil pump being driven directly from the crankshaft. This is a gear pump capable of delivering a maximum pressure of 250 lb. per square inch. The oil is led through the drilled crankshaft to all of the main bearings under pressure and also to the hollow camshaft and hollow rocker arm shaft. The pressure feed, therefore, is directly to the camshaft bearings and also to the rockershaft bearings, from which the oil feeds to the valve driving contact points. The mechanism underneath the

Forward part of Duesenberg eight-in-line chassis

Plan view of chassis.

valve cover plate is really operating in an oil mist, due to the high pressure employed and the large supply of oil forced into the head by the oil pump. The oil return passes over the camshaft driving gears, keeping these supplied with a bath of oil. The breather pipe is on the left rear end of the engine and has a hinged cap. It acts as the oil filling passage, and upon the front of the breather pipe is the oil level indicator gage.

The water pump is a centrifugal impeller type driven by a cross-shaft which receives its drive from the vertical camshaft drive shaft. The cross-shaft terminates at the water pump on the right and on the left delivers the drive through a set of bevel gears to the auxiliary shaft. The fan pulley is in front of the bevel gearcase and behind it the drive is transmitted through a flexible coupling to the generator and distributor, the latter being mounted on the rear end of the generator. An interesting feature in connection with the cooling system is that the water enters the block at the lower right in front and leaves it at a point just above the point of entry. The circulation is controlled by internal baffles.

Gasoline is fed from a 20-gal. tank located at the rear of the chassis to a Stewart vacuum tank mounted on the dash. The 1½-in. Stromberg carbureter is located on the right side of the engine, the gas flow being vertically upward to a hot-spot contact with the exhaust manifold, which is located on this side of the block. From this point the gas is taken through a straight passage between the two center cylinders across the block to the left side of the engine, where it enters the aluminum intake manifold, which is of ramshorn design. This distribution system for the gases is clearly shown in the left-side view of the engine herewith.

#### Suspension System

The flywheel is a steel forging, machined all over, with the starting gears cut in the periphery. The clutch is housed in the flywheel, which latter is inclosed in a bell housing which carries the side arms for two points of the engine suspension system. The third point of suspension is at the front end, where there is a patented trunnion, giving a three-point flexible mounting. The clutch is a single dry plate type and the gearset a three-speed unit, providing ratios in the gearbox of 4.016 to 1 on reverse, 3.167 to 1 on first, and 1.1654 to 1 on second. The rear axle ratio is 4.6 to 1. The drive to the rear axle is through a double flexible joint and a tubular drive shaft, which is inclosed in a torque tube. The thrust of propulsion is also taken on this torque tube, which carries a yoke at its forward end hinged to the center cross-member of the frame. In addition, there are two radius rods which run from the extremities of the rear axle to the front end of the torque tube. The rear axle housing is of molybdenum steel, in one piece, and reinforced. The pinion shaft is mounted on two double-row annular ball bearings. The differential consists of a forged steel case inclosing the spider arm, four bevel gears and two side gears splined for the axle shaft. The hollow axle shaft is of molybdenum steel, the shaft and hub being in one piece. The wheels are Rudge-Whitworth design and are mounted on annular ball bearings.

The front axle is also tubular and the axle ends and steering knuckles are of molybdenum steel. The front axle, which is shown in section herewith, is claimed to be more than 25 per cent lighter than the usual type of front axle and at the same time more than 25 per cent stronger. The axle is so designed as to incorporate the passages for the brake operating fluid.

The brake drums are forgings 16 in. in diameter and are fitted to all four wheels. In order to obtain a perfect

braking surface the drums are ground. Circumferential fins are machined on the outer edges to provide strength with lightness and radiating surface. The four brakes are operated by hydraulic pressure. A master cylinder is connected to the brake pedal and the liquid is forced through the lines running to the four wheels by a piston in the master cylinder. A small cylinder in each of the four brakes has a piston which is forced upward by the liquid entering the cylinder. The piston at the brakes operates a toggle arm which, in turn, expands the two brake shoes in each brake. All four of these brakes are operated simultaneously by the service brake pedal. An interesting feature of the brakes is the fact that, owing to the floating arrangement of the piston and toggle, the brakes are self-centering and, consequently, self-equalizing. Once the brakes are applied, they provide equal pressure against each drum. Water is used as the brake-operating fluid in summer time and an anti-freeze solution in winter.

#### Four-Wheel Brakes

In a demonstration given the writer in one of these cars on the roads around Indianapolis, the braking power of four-wheel brakes was thoroughly demonstrated. On roads which corresponded in surface to the ordinary gravel roads, the car was stopped in approximately its own length from a speed of 30 m.p.h. There was no skidding tendency whatever, and one of the points demonstrated was the ability of the driver to maintain a high average speed on a winding road, because of the quickness with which it is possible to slow down on coming into a curve. An interesting point brought out was the fact that during the time all four brakes are applied the car loses much of its responsiveness to the steering wheel because of the tendency to go into a front-wheel skid with the front-wheel brakes applied. A driver soon becomes educated, however, to releasing the brakes on

Hydraulically-operated front wheel brake

manipulating the steering wheel. The hand brake operates on a drum at the forward end of the propeller shaft.

The car is mounted on semi-elliptic springs, the front being  $2\frac{1}{4}$  in. wide by 40 in. long and the rear  $2\frac{1}{2}$  in. wide by 59 in. long. The springs are equipped with Watson "stabilators." Chrome nickel steel is the frame material, the channels being  $6\frac{7}{16}$  in. in depth by  $2\frac{1}{8}$  in. in width. There are five cross-members. The car has a clearance of  $11\frac{1}{2}$  in. under the front axle and 10 in. beneath the engine. The rear axle clearance is  $10\frac{1}{2}$  in. The bodies are of aluminum with steel fenders, and the equipment includes bumpers and a spare wheel carried at the rear of the car with a three-point mounting. The tires are 33 by 5 in. all-around. Chassis lubrication is by the Alemite system. The price of the car will be between \$6,000 and \$7,000.

## A Constant Compression Engine Cycle

ONE of the chief disadvantages of the conventional throttling four-stroke cycle engine is the fact that its economy falls off rapidly as it is throttled for part-load operation. At light loads the fuel consumption per b. hp. is sometimes three or four times that at full load, yet the average passenger car engine operates most of the time at less than one-third load. Various attempts have been made from time to time to overcome this disadvantage by the use of some constant compression type; that is, an engine in which the compression pressure remains constant regardless of the load. In such an engine it is customary to localize, at least to some extent, preferably in the vicinity of the spark plug, that portion of the charge containing the fuel and to admit through another valve sufficient air to fill the remainder of the cylinder, thus preventing the formation of a mixture too lean to burn.

Patents covering a "cycle" or method of operation of this character have been granted to W. L. Dempsey. In this case a third valve of the automatic type is applied to an engine of conventional four-stroke type. The third valve is located near the base of the cylinder, so that the port to which it is connected is uncovered by the piston at the end of the suction and power strokes. The valve does not open, however, unless the pressure in the cylinder is below atmospheric. It admits only pure air, which, it is assumed, does not mix intimately with the remainder of the charge, but forms a strata next to the piston. The quantity of air taken in is dependent

in part upon the extent to which the engine is throttled, the greater the depression in the cylinder the greater the quantity of air drawn through the automatic valve and the greater the proportion of pure air in the total charge. The carbureter is set to give an over-rich mixture, which is taken in through the main inlet valve, but the air taken in later is sufficient to dilute the total mixture so that it is of correct proportions for complete combustion, or on the lean side.

Considerable increase in economy and other advantages are said to result from the application of small automatic valves to existing automobile engines, but authoritative data in this regard has not been furnished, nor, so far as we are informed, has an engine designed with particular reference to operation on the so-called "Dempsey cycle" been constructed to date.

AN improvement in spring drives for electric starters has been patented to S. W. Rushmore. It consists in making the helical spring used with such drives of tapering section, so that it may be comparatively light or flexible when first beginning to wind up and become sufficiently stiff before the engine is broken loose to prevent abutting of the starter pinion against its stop. It is claimed that when the spring is made of uniform thickness throughout, in order to get sufficient flexibility, the spring is sometimes made so light that it cannot withstand the shock of abutment and breaks.

# Novel Type of Suspension Interests British Car Manufacturers

It is said to have merit of low cost as well as to improve riding qualities. Two-leaf spring attached at two points to chassis frame by rubber blocks runs full length of car and is bolted fast to both front and rear axles.

By M. W. Bourdon

**A** PROMISING new spring suspension system has recently been introduced in England by the Cowey Engineering Co. About a score of British motor car manufacturers are now either testing it on cars of their own make adapted to utilize it or are going carefully into its possibilities. Eight experimental cars have already been fitted up with the system, and one prominent maker has definitely decided to adopt it for his cars which will be produced when his present batch is completed—say about the middle of next year.

The system is simplicity itself and no lengthy explanation is needed to supplement the accompanying drawings. There are two inverted half-elliptic springs, one at each side of the chassis and running without break from the front to the back axles. Each unit consists of two leaves only with, in the case of cars of 15-hp. and over, a wood strip between them over approximately half their length. Each spring is connected to the chassis by two brackets, but is not held rigidly in them, rubber blocks being interposed above and below. Between the brackets a clip encircles each spring, and serves as a means of adjusting the frictional effect between the leaves and the wood strip. The latter is provided to increase the frictional effect, on medium sized and large cars, along that portion of each spring where it has been found desirable to do so, or that is between the frame brackets. Both leaves of each spring are rigidly attached to the rear axle, but one only, the lower, is secured to the front axle, the upper leaf being either cut off 2 or 3 in. short or allowed, if of full length, freedom to move longitudinally over the other.

There are several advantages derivable from this system of suspension. In the first place, it has the low cost

of quarter elliptics front and back without the drawback of imposing localized stresses of considerable magnitude on the side members of the frame where the brackets occur. Then, it has no details requiring lubrication, which obviously means a lower cost as compared with systems requiring greasers, oilers and oil-less bushes, and is a feature which cannot fail to appeal to users by simplifying maintenance.

But where the chief advantage of the system lies is in its behavior on the road. Dimensioned and arranged to suit the individual car, it can have an unusual degree of flexibility without giving rise to a tendency for the car to roll or bounce. It can have a very low period and in some cases this is as low as 55 per min. without drawback in other directions. Further, fore and aft plunging is almost entirely eliminated on roads which encourage that action with ordinary suspensions.

The merit last referred to is due to the "sympathetic" deflection of the opposite end of each spring from that which receives the initial shock. When, for instance, the back axle is lifted relative to the frame by a bump on the road surface the front end of the spring is also affected, a fact which is demonstrated by loading up the back of the car, which has the effect of deflecting the front end to an extent equalling approximately 50 per cent of the deflection at the rear. The accompanying diagram illustrates this point and shows the peculiar curvature which the spring assumes as a result of initial deflection occurring at one end.

The purpose of allowing the springs to float within rubber blocks in the brackets and of securing the top leaf rigidly at the rear end only is, of course, to allow the

The Cowey spring suspension, showing method of attachment to chassis frame and axles. The diagram shows the curvature assumed (heavy line) when one end is deflected 4 in. The other end of the spring is then said to have a "sympathetic" deflection of 2 in.

top blade to move over the other when the spring is deflected at either end. It will be realized that this latter necessitates that the top leaf shall be free to move longitudinally to a limited extent within the brackets and that the lower one shall be able to "roll" within them when its curvature is varied, for the brackets are rigidly bolted to the frame and have no trunnion bearing. Both these movements are permitted by the rubber blocks, but the latter do not vary their position relative to either the blades or the brackets; there is merely a movement within the body of the rubber. When an experimental suspension has been dismantled after being in use for several months, the rubbers have been found firmly adhering to the metal above and below them and have shown no signs

of wear. For this reason the rear ends of the springs are able to take both torque and drive, for the thrust from the latter does not, as might be expected, cause the springs to be pushed bodily forward in their brackets.

The absence of rolling with this suspension is ascribed to the thickness of the individual leaves of the springs, which it is maintained exert greater resistance to torsional stresses such as exist when rolling tends to occur. As an indication of the dimensions of the blades, it may be said that on a heavy car, one weighing say 4000 lb. unladen, each blade is  $2\frac{1}{2}$  in. wide and 1 in. thick.

The Cowey system is being tried out by makers of British cars of almost all sizes, from a 10-hp. two-seated runabout to a seven-passenger car of 30-hp.

## A New Gear for Motor Truck Axles

A RECENT development is a double helical bevel gear for motor truck axles. The outstanding feature of this gearing is the double strength which is claimed to allow the use of very small bevel pinions so that it can give sufficient reduction and still have sufficient strength and road clearance for motor trucks, where it has heretofore been impossible to use bevel gears, and manufacturers have had to resort to the worm or double reduction gearing.

The inventors claim that two 8-tooth, 5-pitch bevel pinions are strong enough for use with a 4-by-5, four-cylinder motor and standard transmission, giving an  $8\frac{1}{2}$ -to-1 reduction with 13.6-in. ring gears, thus allowing 10½-in. road clearance with a 2-ton truck fitted with 36-in. drive wheels. An axle for a 1-ton truck with a  $3\frac{3}{4}$ -to-1 reduction utilizes 10¼-in. ring gears with an 8-tooth, 5½-pitch pinion.

Another advantage claimed by Penrod and Wissel of Cincinnati, the designers, is a complete herringbone balance of all gear thrusts caused by the helical angle of all gears and also complete balance of the separation thrusts on the ring gears, allowing the use of cheaper bearings, a lighter case with at least as high efficiency as where only one set of helical bevels are used.

The two ring gears and bevel pinions are interchangeable and the two spur gears are equal but of opposite inclination of the teeth. For trucks it is cheaper to make two helical bevel ring gears than one of the same strength, as the two and the elimination of gear thrusts

allow the use of much cheaper bearings and case. It is claimed that the loss of power and extra wear from going through one more gear than the single-bevel axle is more than compensated for by the elimination of gear thrusts and the consequent lessened strain on case bearings.

Regarding adjustment of this axle, the inventors state that it is entirely unnecessary after it is correctly assembled, as it will remain in adjustment, due to the balance of all gear thrusts. The ring gears may be ground to the correct thickness after they are heat-treated and hardened.

## Depreciation and Its Relation to Cost

A N interesting paper on "Depreciation—Its Relation to Costs and Financial Statements," was read recently by C. A. Porter, comptroller of the Hardinge Company, at a meeting of the New York section of the Industrial Cost Association.

There are four main factors, Mr. Porter said, to be taken into consideration in making up depreciation schedules—length of life, cost of repairs, obsolescence and inefficiency. A perpetual inventory of the physical assets of any plant was recommended. This record, commonly called a plant register, should contain an individual sheet for each building, each machine and each major piece of equipment. Small tools should be listed on one sheet for each department.

This plant register should show, among other things, the date a machine was installed, location, description, builder, original cost, cost of installation, total cost, anticipated life, rate of depreciation, depreciation to date and the disposition, if any.

While Mr. Porter's paper was interesting and practical from many standpoints, the question of obsolescence, which is most important to the automobile manufacturer, was not thoroughly gone into. A discussion of the subject, following the paper, brought no tangible solution to this perplexing problem. Several members of the association pointed out that too great an allowance for obsolescence could not be made in writing off depreciation because the Government would not permit it in income tax returns. Others contended, however, that if a body of manufacturers agreed that a certain tool or machine was likely to become obsolete, or superseded by a newer and better machine within a few years, the Government officials were tolerably lenient in this respect and would allow the factor of obsolescence to appear in the depreciation items.

Installation of Penrod double spiral bevel gear for rear axle reduction

# A New British Traction Dynamometer

A description of a recording instrument designed especially for use in tractor trials, registers drawbar pull, time, and distance covered. It requires little attention from observer over several hours' operation.

**A** NEW draw-bar dynamometer outfit designed by G. W. Watson, engineer to the organizers of the British Tractor Trials, was demonstrated in practical use at the recent trials near Shrewsbury, England. Eight instruments were in constant use for several days, every competing tractor having one interposed in its coupling to the plow for six consecutive hours.

The complete testing outfit consists of three units:

- (1) The draw-bar dynamometer unit, which is intended to be coupled in series between the tractor and plow, etc.
- (2) A small case carried on the tractor containing a dry-battery and clock mechanism provided with electric contacts, and
- (3) A depth measuring attachment, which is intended to be secured to the frame of the plow, cultivator or other implement.

It is claimed that neither the main unit nor any detail of the outfit is a laboratory instrument, but that the whole outfit is a commercial testing apparatus of robust construction, and calculated to stand the severe conditions of service in the field or on the road in the hands of semi-skilled attendants. Previous units of this kind which have been supplied by the National Physical Laboratory, Teddington, England, for use at British tractor trials have, on the other hand, required careful handling and

skilled attendants and necessitated the latter being constantly at hand. Nor have they been composite units, the recording apparatus being carried by one of the men in charge walking alongside the plow coupling.

The Watson dynamometer unit can be coupled up to the tractor and time clock, loaded with a roll of paper, and left to its own resources during six hours' continuous plowing at an average speed of  $2\frac{1}{2}$  m.p.h., the limitation of time being merely concerned with the length of the roll of paper carried.

The main unit is mounted on a tubular T-shaped frame and runs on two cast iron wheels, one, of considerably larger diameter than the other, serves to rotate the paper rolls by means of bevel gearing and a flexible shaft.

The base and end plates of the recording instrument are carried by a pivot post attached to the single member of the tubular frame in such a manner as to allow the axle to swing sideways or vertically and to accommodate itself to inequalities of ground surface. Part of the weight is supported by a pair of leaf springs acting as shock absorbers and keeping the wheels in contact with the ground, while the pivot post end is connected to the tractor draw-bar by means of a semi-rigid coupling so that approximately half of the weight is actually carried on the draw-bar, but as the whole outfit weighs only 60 lbs., this is not a serious matter. The rear end of the draw-bar unit can be connected by chains, etc., to the implement which is being hauled.

Applying to the paper roll are three stylus points, the central one indicating the draw-bar pull, another the elapsed time by diversions from the straight line at intervals of half a minute, and the third the plowing depth. The time stylus is controlled by the time clock already referred to, while the depth recorder is actuated by the movement relative to the plow frame of a small castor wheel running on the unplowed land and carried by means of a bracket and hinged fork attached to the plow frame.

Of the various methods by which the stylus can be made to record, it has been decided to make use of a metal point with a roll of carbon paper under the roll of plain paper, for this plan has been found to be more uniformly satisfactory for tests over long periods; a pencil becomes blunt, an inking pen may dry up and a metal point for marking on metallic paper has also proved deficient in practical use. The draw-bar unit therefore carries four paper rollers, two of these being for unused and used plain paper and the other two for unused and used carbon paper.

The main unit frame is built up of two stout end plates and a base plate, supporting between them the main hydraulic cylinder and piston, the end flanges of the cylinder being securely bolted to the end plate of the frame. The piston pin projects through a hole in one of the end plates, and to it applies a hardened steel ball recessed in the upper end of a rocking lever, to the lower portion of which is coupled the chain or other connection to the plow. But in order to ensure that no distortion of the dynamometer frame shall occur in use, this rocking lever is pivoted to the rearwardly extending ends of two

Close up view of main unit of Watson recording dynamometer showing three stylus levers and other details

Sample of record from Watson dynamometer. Perforations not visible indicate distance covered

tension links, which pass with clearance through the frame at both ends and are secured at the front to the pivot post of the instrument. But for this arrangement the whole of the frame work of the recording apparatus would have to be made far more substantial, and would then possess a great disadvantage in excessive weight. The lower portion of the ball-ended lever is provided for two holes, the lower one being intended for use when coupling up to implements with a draw-bar resistance up to 3,000 lbs., and the upper one for draw-bar effort up to 6,000 lbs. When a pull is applied to the lower end of the lever, the ball at its upper end presses on the exposed end of the hydraulic piston, but the maximum pressure at any time created by the loads mentioned does not exceed 500 lbs. per sq. in.

The main hydraulic cylinder is connected to a smaller cylinder and piston, the latter operating the stylus in the same way as a steam-engine indicator. The total range of this smaller piston is only  $\frac{3}{8}$  in., but by means of multiplying levers, the stylus point has a range of 3 inches on the chart, and by a special system of linkage the actual movement of the stylus point in either direction is practically a straight line. The indicating piston is forced out of its cylinder against the resistance of a calibrated spring, which yields in direct proportion to the pressure created in the main cylinder. By thus limiting the movement of the small piston and spring to  $\frac{3}{8}$  in., the inertia effect becomes practically negligible. Positive stops are provided for the indicator piston, so that the stylus levers never carry any portion of the load.

The rate of paper feed is determined by passing it half round a feed roller with pin projections, this roller being driven by the flexible shaft and gearing from the measuring wheel which bears on the ground. The feed of the paper is therefore directly proportionate to the travel of the dynamometer and is approximately  $1\frac{3}{8}$  in. per 100 ft. of travel. The pin projections in the feed roller perforate the paper and are so spaced that the distance be-

tween any two perforations represents 25 feet of travel. The rollers which receive the chart and the used carbon paper are friction driven from the feed roller, so that, as the diameter of these rollers increases with the amount of paper rolled on them, slip can take place and damage to the chart is avoided.

The time indicating stylus normally inscribes a continuous straight line, but at each half minute a kink is made in the line by the stylus being moved laterally by an electro magnet.

With regard to the depth indicator mechanism, the fork which carries the small castor wheel running on the unplowed land is actually a bell-crank lever, and once the vertical position of the pivot of this bell-crank lever has been adjusted to suit the plow, it remains constant throughout the test. As the plow shears and the frame to which they are attached sink in proportion to the depth of plowing, proportionate movement is given to the bell-crank lever, the short end of which exerts a pull on a Bowden wire coupling with the recording instrument, and thus allows the lighter of two springs to force the stylus lever sideways to indicate the depth of furrow. When the depth of plowing decreases the stronger spring is more or less released; it therefore compresses the light one and forces the stylus lever back towards zero.

It will be noted from the foregoing that the depth recorder indicates the average depth of the two or more furrows being plowed and not the depth of individual furrows, but obviously the latter is not required to be known in taking a record of the total work done by the tractor. The records produced by the instrument can be easily integrated to obtain average pulls and depths, and from the markings of time and distance the speed can be plotted.

Every moving portion of the outfit is completely enclosed, with provision for adequate lubrication, and a dust cover with transparent sides is provided to encase the paper rollers and stylus pins.

Diagram showing how the units of the Watson drawbar dynamometer outfit are coupled up to or carried by tractor and plow

# Use of Wrought Aluminum Alloys in Automobile Construction

The advantages of wrought alloys are discussed together with the possibilities for use of aluminum in automobile construction. Not all engineers will agree with Dr. Rosenhain in every particular, but this discussion by a recognized authority is worthy of serious attention.

By Dr. Walter Rosenhain, F.R.S.

**W**HILE it is undoubtedly the function of the designing engineer to select the materials which are to be employed in the construction of his machines, he is yet dependent upon the metallurgist for those materials and, in the first instance, for his knowledge of their properties. Particularly is this true where materials of a more or less novel kind are concerned. Therefore, the metallurgist who is well acquainted with them is in a position to offer suggestions which may prove of value to the designer. It is in this spirit that the question of the utilization of aluminum alloys in automobile construction is treated in this article.

Light alloys of aluminum are, of course, already used to a very considerable extent in various ways in existing automobiles and an attempt has been made to produce an "all aluminum" car. Yet in the majority of designs steel predominates and light alloys are only used for special purposes, such as the aluminum piston which has been discussed in considerable detail, and for more or less subsidiary castings, such as crank-cases, gear-boxes, etc. In the latter cases the principal, if not the sole, reason for employing aluminum alloys is the desire to save weight. Indeed, apart from the pistons and cylinders, where thermal conductivity enters so largely into the problem, the saving of weight is the main advantage to be gained by the use of aluminum. The principal question is, how far this can be pushed with advantage.

The majority of engineers have hitherto confined their attention to the use of aluminum alloys in the form of castings. The advantage in the use of wrought material, however, makes itself felt in several ways. In the first place the wrought alloys now available afford material of very much greater strength. Taking tensile strength as a rough measure, ordinary castings rarely exceed a figure of 30,000 lb. per square inch and even the best modern heat-treated castings of the alloy now coming to be known as "Y" only attain a maximum of 45,000 lb. and this is at best combined with an extension on 2 in. of 5 or 6 per cent. On the other hand, both "duralumin" and rolled or forged and heat-treated "Y" can readily be obtained giving up to 60,000 lb. with a ductility that shows an extension of 18 or 20 per cent on 2 inches. Further, the fatigue-resisting and other properties of these wrought alloys are far superior to the best castings. If it is desired to push tensile strength

to its highest limits, values as high as 88,000 lb. combined with an elongation of 12 per cent on 2 in. can be obtained in alloys which are quite satisfactory if thoroughly protected from corrosion.\*

Quite apart from their very much greater strength, particularly in regard to shock and fatigue, the wrought alloys possess a most important advantage over the cast material in regard to reliability. Even the best of castings are apt to be, at times, more or less unsound and it is often difficult, if not impossible to discover the existence of defects. In wrought material, on the contrary, serious unsoundness is substantially impossible. In the first place, material intended for rolling or forging is always cast into simple ingot forms in which soundness can be readily achieved, since they are free from the serious difficulties which occur in complicated castings where thick and thin portions are expected to solidify together. Further, should a defective ingot be produced, it generally shows signs of the defect during the forging or rolling operations—these operations, in fact, constitute a severe and thorough test of the homogeneity of the material, particularly in aluminum alloys in which the first stages of "breaking down" from the cast condition are always delicate and somewhat difficult. It would seem, therefore, that wrought material is in many ways superior to cast.

One consideration which must, of course, affect the designer's judgment on such a point is that of the relative cost of the two types of material. This can, in the long run, be decided only when actual market prices of castings and forgings or built-up parts are actually available. At the present time wrought material is not yet widely available and in many cases its price is high owing to the fact that heavy royalties on patented alloys have to be covered. The extension of our knowledge of the range of available alloys should soon overcome this difficulty, while the question of available manufactures is simply one of demand.

## Parts in Which Alloys Can Be Used

The next point of interest centers on the question for what parts of an automobile can wrought aluminum alloys be employed. The answer is not easy to give without considering in detail the design in question, but, broadly speaking, it may be said that apart from parts in which great hardness and resistance to wear is essential, there is probably no limitation to the application of the light alloys. It is not suggested, of course, that this application will necessarily be wise or desirable in every case, but only that it is in most cases perfectly possible. It is obviously impracticable, in the limits of

\*The figures briefly quoted above, together with full details concerning the composition and treatment and general properties of the alloys in question, will be found in the Eleventh Report to the Alloys Research Committee of the Institution of Mechanical Engineers, London, 1921. Since this report occupies more than 250 pages, it is obviously impossible to reproduce the details in the space of the present article, but readers interested in them can readily refer to the report.—W. R.

the present article, to go into any great amount of detail with a view to showing how such an adaptation could or should be made. All that can be attempted is to take a few typical examples by way of illustration and suggestion.

The aluminum alloy piston—by which is meant the cast piston—is already in extensive use and gives considerable satisfaction. Yet even here the use of forged material would offer undoubted advantages, particularly from the point of view of soundness and reliability. A good many existing pistons are, of course, of a shape which could not be readily produced even by considerable machining from any reasonable forging or pressing. It may be suggested, however, that these designs are perhaps needlessly complicated. The internal ribs, for example, are mainly a concession to the supposed weakness of the material; if the piston were made of forged material of considerably greater strength, these ribs could probably be eliminated and—if necessary—replaced by slight thickening of the piston wall.

Very satisfactory piston designs have, in fact, been produced which can be made quite cheaply and easily from a simple forging. This is of the form of a cylindrical block having a central depression or hole. This leaves a wall-thickness great enough to allow the bosses for the gudgeon-pin bearings to be left when the forging is machined internally. Ultimately, however, it may be found possible to press the pistons, not in the form of a nearly solid cylindrical block, but in the shape of a fairly thick-walled cup made from a thick flat disk of rolled alloy—much as a cartridge case is pressed from a strip of sheet brass.

#### Difficulties Encountered

The piston is an example which presents, by comparison, somewhat considerable difficulties. A complicated object such as some of the intricate crank-cases and cylinder blocks now employed would present even greater difficulties, and in those cases it is no doubt a very open question whether the use of wrought material would be in any sense worth while. It would probably imply the use of built-up parts which would require a considerable amount of machining and fitting together. An appreciable saving in weight could probably be secured but whether the built-up article would be as thoroughly satisfactory as present day castings is doubtful.

Before leaving the engine mention must be made of connecting rods and crankshaft. So far as the latter is concerned, the use of anything but steel cannot as yet be regarded as a practical possibility. It is true, of course, that at first the use of an aluminum alloy even for a piston was regarded as entirely impossible, but in the case of a crankshaft even preliminary experiments have yet to be made. In regard to connecting rods, however, the matter stands in a very different position. Engines have been run successfully and under severe conditions with aluminum-alloy connecting rods. In some of the trials these were made of precisely the same dimensions as the steel rods which they replaced and yet they operated with entire success. This is perhaps asking rather too much of any light alloy, but with a suitable increase in dimensions—while still leaving a considerable margin of reduced weight—there is no reason to anticipate anything but the best results. The use of these lighter rods will further improve the running of the engine, so that here there would seem to be a fruitful field ripe for an early advance.

Perhaps the most important application of wrought aluminum alloys in automobile construction will be found in the construction of the chassis or under-frame.

Here there is the possibility of a very appreciable and important saving in weight with all its concomitant advantages—saving in engine power, in wear on tires and particularly in the power expended and lost in frequent starting and stopping and in rapid changes of speed on the road. Here there can be little doubt as to the practicability of replacing steel by a suitable light alloy. Attempts have, indeed, been made to produce a satisfactory cast-aluminum chassis and the resulting object has given remarkably good performance. None the less, the general considerations stated above in favor of wrought material apply with very special force to the chassis. The shape of the object, to begin with, renders it difficult to cast satisfactorily, and if it has to be built up there is no advantage in using cast rather than forged or rolled parts. The only difficulty at the moment is that suitable sections of rolled aluminum alloys are not commercially available, but here again it is entirely a question of an adequate demand.

#### No Technical Difficulty

There is no serious technical difficulty in the way of the production of any desired section in a light alloy if the same section can be produced in steel. The difference is that steel-makers have for long years been accustomed to producing heavy sections and forgings of considerable size, while hitherto manufacturers of aluminum alloys have had no occasion to deal with such objects. It thus becomes a matter for enterprise on both sides and for co-operation between two industries which may well become to that extent interdependent.

The question of the relative dimensions of a part made of wrought aluminum alloy as compared with steel is not easily settled. The actual working stresses in such parts are not really known with any degree of accuracy, particularly in regard to shock and fatigue. The dimensions of the steel parts themselves are, in the majority of cases, determined by judgment, based on experience, rather than by exact calculation, so that it is never very certain whether they are just strong enough or actually very much stronger than is essential. Taking the existing steel construction as a guide, however, it may be borne in mind that the best of the wrought aluminum alloys have about the same tensile strength as a mild to medium-hard steel. So far as "static" strength is concerned, therefore, it would seem safe to replace such steel with aluminum alloy of the same dimensions. Unfortunately, however, the light alloys have not as great a resistance to fatigue stresses as mild steel, and where such stresses are mainly operative it would seem wise to allow something like double the dimensions, or, rather, one-half the working stresses which are allowed in steel.

It must, of course, be borne in mind that by increasing the dimensions of a part acting as a beam, for instance, its stiffness is increased much more rapidly than its strength, and where fatigue stresses are mainly due to vibrations set up in the structure itself this increased stiffness must be taken into account, since it will serve to reduce the alternating stresses arising from vibration.

The question of stiffness raises the interesting point as to the application of light alloys in springs of various kinds. Here the lightness of the material and its relatively low elastic modulus—about one-third that of steel—suggests very promising applications. Some rudimentary experiments in that direction have given promising results, and it seems probable that in this particular field there is an immediate possibility of an important advance. In springs made of wrought light alloys it will, of course, be necessary to keep the working stresses relatively very low, but this necessity is more

than counterbalanced by the lightness of the material and its low elastic modulus, which allows, on the one hand, of the use of very much larger springs and at the same time permits considerable amplitudes of deflection without high working stresses.

Without having in any way exhausted the various possible applications of wrought light alloys in automobile construction, the examples which have been given will perhaps be sufficient to indicate the lines upon which application of these materials is suggested. It is, of course, a process which will require watchful care on the part of the designer and in the factory, but the possibilities of advance are very considerable and it is a course which is already being actively pursued in various quarters. The "all-aluminum car" may not yet be an achieved practical success, but it is likely to be so before long.

#### Question of Corrosion

There is, however, one point which demands serious consideration and that is the question of corrosion. There is no doubt that all aluminum alloys are more or less easily corrodible, but, after all, so is steel. In the case of steel we have learned to afford it fairly efficient protection. Our enamels and paints and other protective coverings are not perfect, but they suffice to give our structures a very good length of life, provided that they are efficiently maintained. There is no doubt that the same degree of permanence can be attained in regard to aluminum alloys. The real difficulty in regard to these materials arises from the fact that at one time it was widely supposed that aluminum was practically incorrodible. This idea no doubt arose from the fact that a brightly polished aluminum article left exposed to ordinary air, but not to rain, etc., remains bright for a very long time. Unfortunately, this power of resisting atmospheric corrosion does not measure the

power of resisting more severe conditions. Alloys are known which will stand for many years exposure to the air in a room, but which will literally fall to pieces if immersed for a few hours in sea water.

Now the question arises, which of these two types of conditions as regards corrosion have we to meet in the parts of an automobile? It is, of course, obvious that these are not exposed to anything even remotely so severe as continued immersion in the sea. On the other hand, they are liable to be exposed to rain and even, at times, to sea air. Actually, even the more corrodible aluminum alloys show very little deterioration if exposed entirely unprotected on an automobile. Yet such unprotected exposure is not essential or even desirable in the important working parts. A large proportion of these parts in any case becomes coated with oil from the engine, gear-box, differential, etc., and this oily coating in itself affords very good protection from corrosion. At the same time there is no reason at all why any exposed aluminum alloy—other than in ornamental fittings—should not be well coated with protective varnish, paint or enamel. Such coatings, if well applied and of suitable composition, afford complete protection from anything to which an automobile is likely to be exposed.

But it is or will shortly be possible to go considerably further than this, as chemical processes have recently been worked out and in certain cases patented for covering aluminum alloys with a protective coating of a very perfect kind. One of these coatings is said to consist of a mixture of the sulphide and oxide of molybdenum which adheres very firmly and serves as an excellent protection, although possibly not entirely resistant to the direct action of sea water. It may, therefore, be safely suggested that the corrosion difficulty, in so far as it exists in regard to automobile work, can be satisfactorily dealt with by these means.

## A Rubber Compound Battery Box

**R**UBBER compound battery boxes to replace those of wood containing hard rubber jars are now being manufactured by Rub-Tex Products, Inc., of Indianapolis. Many attempts have been made to make boxes of hard rubber, but it has been found that these boxes are too brittle and do not stand up under the freezing test. The Rub-Tex compound is made from a secret formula and it is claimed both these points have been overcome. In addition, it is claimed that these boxes overcome the difficulties encountered with pin-holes, blow-holes and other forms of leakage, which are common with hard rubber products.

In order to overcome these defects the Rub-Tex box is made by building the battery box up by hand, thereby laminating each piece of rubber and overlapping each piece at the corners. The boxes are then cured under very high pressure.

Battery manufacturers have been making tests on this type of box and, according to the Rub-Tex company, the box has stood up under a number of very difficult tests, among which is the following:

A box with the elements installed was placed in a refrigerator at 26 deg. below zero and left for a period of 48 hr. After this period the box was examined and found to be in an entirely satisfactory condition.

Another test was to install the elements in a box and place it upon a bumping machine. The box was given one million bumps, after which the elements were re-

Battery box built up by hand and moulded under high pressure

moved and the bridges at the bottom of the cells are claimed to have shown very little if any wear.

A further test was made at the Detroit Testing Laboratories of Detroit, which gave the box a heat test for a period of 16 days ranging from 65 deg. Fahr. to 175 deg. Fahr., upon which a certificate was issued to the effect that there was no change in the color of the acid or in the consistency of the material. The box is claimed to have a dielectric strength of in excess of 26,000 volts.

The compound of which the box is made, it is claimed, has the ability to resist absorption of water or acid. The jars and box are combined in one unit, which gives it considerable structural strength besides that imparted by the physical qualities of the material.

# Investigation of Tooth Wear With Automobile Gear Steels

Steel with a minimum of 0.45 carbon that is capable of treatment giving a scleroscope hardness of 75 or over is recommended for oil treating. The specification limits should be close enough to insure uniform results from a standard heat treatment. Various steps in the tests are described.

By E. R. Ross\*

**F**URTHER investigation is needed to establish reliable data relative to the various factors that determine the smooth operation and life of gear trains. The research work could be divided under three headings, as follows:

1. An investigation to establish the most suitable material for use under given conditions, the allowable stress, allowable pressure, resistance to abrasion, and elasticity being found for different materials.
2. Investigation of methods of manufacture, with an

Fig. 1—Outline drawing of Warner transmission on which tests were made

attempt to define the degree of error permissible with various grades of workmanship.

3. A determination of the influence upon the life and quiet operation of gears of such variables as peripheral velocity, load per unit of width, number of impacts, ratio of reduction, grade of workmanship, heating and disposition of metal in the gear rims and arms. Methods of gear mounting to absorb vibration, and the lubrication of gears also would receive attention.

It will be agreed that successful research along these lines would provide dependable data for the design of gears to meet any conditions in regard to load, speed, quiet running, life, etc. Alone, the Lewis formula can be used only to ascertain the maximum permissible load to insure freedom from tooth breakage, and unfortunately with many gears this is the only point

checked by the gear designer, with the result that gears are transmitting excessive pressure so that backlash and noise develop in a very short time.

With this outline before us in compiling the data of our tests, we have attempted to solve, in a measure, some of the most important problems that face the gear manufacturer to-day. The work we are now doing has been confined largely to the selection of materials best suited for the purpose of automobile transmission gearing, the selection being upon the basis of resistance to abrasion or wear. Two of our standard transmissions (Fig. 1) were used, which were checked over very carefully. We then proceeded with the tests by alternating the two, preparing the one while we were testing the other. All parts were checked carefully after tearing down the transmission; likewise all new parts were carefully checked before assembling.

This transmission has 6/8 pitch gear of 3/4-in. face and is well adapted to the needs of a medium weight and medium powered passenger car or light weight truck. The test was run on the second speed gears, or the third and fourth of a train of four gears (shaded in Fig. 1). This pair was selected because it is the most used of the speed reductions in passenger car service, and also on account of the difficulties presented by the manufacture of a sliding gear with internal clutch teeth. It is frequently used with a very high percentage of the full motor torque. These are "clash gears," and accordingly a portion of the face width has to be sacrificed in rounding the corners at one end of the teeth. As compared with the other reductions, a higher pitch line velocity is here combined with lower maximum torque.

In order that we might duplicate the conditions of individual tests, constant torque and constant speed were first considerations, and for this reason, standard dynamometer equipment was used.

Fig. 2 shows the set-up for the tests. The transmission is mounted on a suitable test stand which carries a stand-

Fig. 2—Test set-up

\*Experimental engineer, Warner Gear Co. Article is slightly condensed from paper presented at Rochester meeting of American Gear Manufacturers' Association.

Fig. 3—Tooth profile indicator

ard bell housing and flywheel and is fitted with large roller bearings. Power is supplied to the transmission by a Sprague dynamometer, so the torque and speed can be accurately checked at all times. At the rear end the transmission connects to a second Sprague dynamometer by which the amount of power transmitted through the transmission could be checked.

A standard grade, heavy transmission oil was used both in the transmission and on the bearings in the test stand, new oil being used on each test. A thermometer inserted in the filler cap and extending down to the countershaft gear in the lower part of the case, indicated the temperature of the oil in the transmission.

#### Tooth Profile Indicator

To be able to properly classify our results, it was necessary that very careful measurements be taken of both the new and worn tooth, and for this purpose we developed a tooth profile indicator, (Fig. 3).

The gear is mounted on a stud in the center of the instrument. At the left, and pressing against the top and side of a tooth, is a stop which is held in this position by the spring behind the block. This holds the gear rigidly in position. Diametrically opposite this stop on the gear there are two fingers carrying points over the edge or profile of the tooth. At the right are two dial indicators, one for each of the points, which operate through a 1:1 lever. To the right of these and in the center is a third dial indicator. This is used to determine the depth or distance in from the point of the tooth to the points of the indicating fingers. The indicating fingers carry sharp points so that their leverage does not change from the 1:1 ratio and the indicators give a true indication of the contour of the gear tooth.

From the readings, plots of the gear teeth were made on a  $7\frac{1}{2} \times 10$  curve sheet, with an enlargement of 25. With this magnification, when the base circle and pitch line are located, when corrections are made for variation in the diameter of the gear blank and the curvature of the pitch line, several very interesting things may be observed.

Referring to Fig. 4, the shaded portion of the tooth is the amount of metal that has been worn from its face, showing the location with reference to the pitch line and base circle. The point of maximum wear upon the gear represented in the lower left hand corner was 0.012 in. deep and

from 0.010 to 0.020 in. above the pitch line.

Since the wear is often unequal and we are unable to predict before the test just where it will be greatest, we select for measurement the tooth that shows the most wear. Fortunately, the chamfered end of the mating gear leaves an unworn portion which can be measured after the run, enabling us to compare it with the worn portion of the same tooth. The plot is a comparison of the original outline with readings taken

in the center of the worn portion of the tooth.

Plots (Fig. 4) are from the second speed sliding gear (below) and the countershaft second speed gear (above), the material used in Test No. 6 being S A E No. 2345, having a hardness of 70 scleroscope. The gears were of 6-8 pitch and 20 deg. pressure angle, having 20 and 22 teeth respectively. The teeth had a  $\frac{9}{16}$  in. width of face in contact at the pitch line. The analysis given with limits is the standard specification for the material used, the figures in parenthesis giving the actual analysis of these gears. The heat treatment given this set of test gears consisted in heating to 1380 deg. F., followed by quenching in oil and drawing in oil at 400 deg. for 20 minutes. From the main drive gear to the countershaft drive gear the reduction is in the ratio of 27:15 or 1.8:1; from the countershaft second speed gear to the second speed sliding gear it is 20:22 or 1:1.1, making a total reduction of 1.636:1. A 50 hp. load was applied to the transmission by the dynamometer (175 lb.-ft. torque at 1500 r.p.m.) continuously for six hours. This represents an overload for this particular set of gears, being quite beyond anything to which they would be subjected in service. Preliminary runs demonstrated, however, that some such overload was necessary if we were going to have any measurable amount of wear in a test of reasonable duration. The six hour test would represent, in a car having 32-in. wheels and a  $4\frac{1}{4}$  to 1 axle ratio, running on the

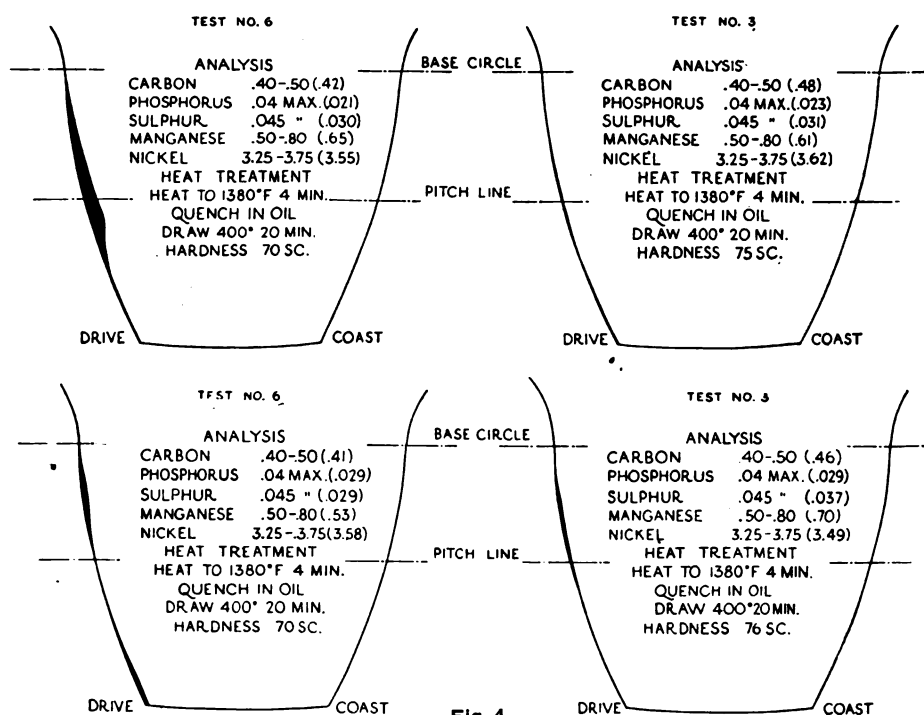

Fig. 4—Plots showing wear of tooth faces of driving (above) and driven (below) gear of S. A. E. No. 2345 steel drawn to scleroscope hardness of 70 (plots on left) and 75 and 76 (plots on right)

Fig. 5—Micrographs of steel in the gears of the plots (Fig. 4) showing finer grain structure of the harder steel

intermediate at a speed of 19 m.p.h. for a total distance of 114 miles. The transmission lubricant used was an oil designated as No. 1 heavy.

The test was conducted by holding the speed and torque of the driving dynamometer constant for the 6 hours, readings being taken of oil temperature, mechanical efficiency and room temperature at one minute intervals for the first five minutes, ten minutes after the start of the test, and at ten minute intervals thereafter till the end of the test. A given amount of the new lubricant was placed in each transmission when "set up" for the test and this was not changed during the test.

#### Minimum and Maximum Wear

Fig. 4 represents the best and worst conditions of wear on the oil treated gears tested. Both are of S A E 2345 steel, heat treated in the same manner and produced by the same cutter, but in Test No. 6 (at the left in Fig. 4) both the gears had a scleroscope hardness of 70 while in test No. 3 (at the right) the scleroscope hardness was 75 for the countershaft gear and 76 for the sliding gear. Note the variation in the analysis of these gears, as well as the relation between the carbon content and the amount of wear. In the latter connection it will be noted that the wear is greatest upon the driving gears, even though it may contain slightly greater carbon. This is a condition which would be expected when the action of the gears under load is analyzed. If the two gears had no backlash, any movement of the driving gear would correspond to an equal movement of the driven gear. In actual gears there is a certain amount of backlash to allow for lubrication, slight inaccuracies in the cutting of the teeth and warpage from heat treatment. Any increase of backlash due to wear permits an uneven or slightly intermittent velocity, which, once started, rapidly destroys the contour of the tooth. This action is more rapid on the driving gear, because it absorbs the variations in load and velocities resulting from the breaking down of the curvatures of both the driving and driven gear.

#### Gears from Same Cutter Compared

In order that we may get a representative test of the wearing properties of the steel and not a premature breaking down of the tooth curvature due to intermittent velocities or interferences, great care must be exercised in the selection of the cutters used for the gears to be tested, and for the other gears in the gear train under load at the same time. In order to eliminate all possible variation of the load in being transmitted through the

first pair of gears in the train, new gears were used for each test. The heat treatment used was either that recommended by the manufacturer of the steel or what we had found by experience best suited to the steels used.

Fig. 5 shows micrographs of the gears of Fig. 4, left and right respectively. The coarser structure of the two steels at the left will be readily seen, and the relative proportions of martensite and troostite. Each steel had a scleroscope hardness of 70, the carbon content being 41 for the upper micrograph, and 42 for the lower. The two steels on the right are of a finer grain, of 65 and 76 scleroscope hardness, and have a carbon content of 46 for the upper and 48 for the lower micrograph.

A collection of 325 separate analyses of S A E 2345 steel shows that the carbon averages between 0.43 and 0.47, the manganese between 0.56 and 0.68 and the nickel between 3.36 and 3.50 per cent. The S A E limits on this steel are so wide that it is difficult to get a uniform structure from a common heat treatment in quantity production.

#### Effect of Carbon Content on Wear

Fig. 6 gives the analysis of the S A E 2345 steels used in tests Nos. 6 and 3. The average analysis is shown as the shaded portion between the dotted lines. It will be noted that the gears of test No. 3, which had the least amount of wear and the higher hardness, show a higher carbon content, a higher average manganese, and about the same average nickel as compared with the gears of test No. 6 which were softer and wore more rapidly. This will also be explained in a measure by the difference in the structure as shown by the micrographs of Fig. 5. The presence of more troostite in the gears having the low carbon may be accounted for when we consider that when a heat is used that is correct for the steel having the higher carbon, it is not high enough for the one having the low carbon content.

The gears of Fig. 7 are of the same material, with a difference in hardness of only three points. Here is very clearly illustrated the point mentioned before in regard to the importance of using gears cut with cutters having as nearly correct outline as possible. The gears of test No. 10 were cut with the same cutters as those of tests Nos. 6 and 3, but during the interval the cutters used for the countershaft gear had cut 240 gears and had been ground eight times, while the cutters used for the second speed sliding gear had cut 142 gears and had been ground five times. This change in the cutter gave an interference which was noted before the gears were tested. When this condition had been removed by getting the proper

Fig. 6—Analysis of S. A. E. No. 2345 steel used in Tests Nos. 6 and 3

Fig. 7

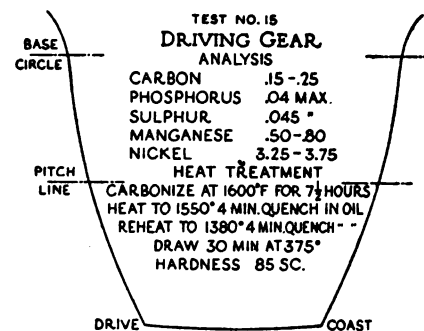

Fig. 8

Fig. 7—Plots of tooth wear from gears produced with worn cutters

Fig. 8—Wear plots from case hardened nickel steel gears

curvature, the steel showed up very well, as will be noted from test No. 12.

#### Prevalence of Pitting

A comparison was also made between Test No. 12 and Test No. 3, both on gears of S A E 2345 steel. As before stated, the tooth showing the most wear was selected and indicated as representing the wear of that particular gear. In this instance the wear of the countershaft gear of Test No. 12 was measured on the only tooth that showed any particular breaking down. Three other teeth showed a very slight pitting, and the remainder of the teeth had bright burnished surfaces, scarcely having the tool marks worn from the gear face. The gears showed the following proportions of the whole number of teeth "pitted:"

Test No. 12 second speed sliding gear, no teeth pitted  
countershaft second speed gear, 18.18 per cent of pitted teeth.

Test No. 3 second speed sliding gear, 17.65 per cent of pitted teeth and countershaft second speed gear 84.2 per cent of pitted teeth.

Fig. 9—Assembly of driving and driven faces

The steel used in Test No. 12 was a very "clean" steel and could be machined very much faster than S A E 2345. The latter steel has a great number of slag and cinder inclusions, which I believe to be a large factor in accounting for the pitting of this steel as compared to the steel used in Test No. 12.

A steel in all respects the same as used in Test No. 12 (48 to 51 points carbon and 77 scleroscope hardness) was tested by breaking two teeth out of the gear. The fracture in either case showed no tendency to be brittle but, on the other hand, was extremely tough, the teeth being broken out with considerable difficulty. The blanks as machined had a scleroscope hardness of 34 to 38 and a corresponding Brinell hardness of 207 to 228. No difficulty was experienced in machining this steel.

#### Oil-Hardened vs. Case-Hardened Steel

Fig. 8 shows test results obtained with S A E 2320, which is a case hardening steel having the same nickel content as S A E 2345 used in Test No. 3 (Fig. 4). Here again most of the wear comes on the driving gear. S A E 2345 has been substituted for 2320 largely because distortion in heat treatment causes it to be more noisy than an oil treated gear. An oil treated gear is not subjected to as high heats, and the length of time the gear is at high temperature is very short, which tends to decrease the distortion. The machine marks were still upon the S A E 2320 gears after the test and the gears showed no pitting whatever.

Fig. 9 is an assembly of the driving and driven profiles of seven tests ranging from the condition of the most wear as shown by Test No. 6 at the left, to the condition of minimum wear as shown by Test No. 15. The driving gear is the one at the lower left of each combination. This gives some idea of the relation of wear to hardness.

Here we may also study the progression of wear. Attention is called to the small worn portion of the driving gear of Test No. 15 at approximately 0.040 in. above the base circle, and also to the worn portion near the top of the tooth. Conditions in Tests Nos. 12, 13, 7 and 6, show how this action progresses, the destructive action having moved from slightly above the base circle up toward the

top of the tooth. Once this action has started on the faces of a gear, it progressively grows in intensity.

### Oil Temperatures and Efficiencies

Fig. 10 shows the oil temperatures, mechanical efficiencies and room temperatures of test No. 15 on the S A E 2320 gears. As before stated, readings of oil temperature (from a thermometer inserted in the filler cap in the side of the case), readings of power output and room temperatures were taken at one minute intervals for the first five minutes, again ten minutes after the start of the test and at ten minute intervals thereafter. At the start of the tests the oil temperatures and room temperatures were the same and ranged from 60 to 80 deg. F. The oil temperature rose very rapidly for the first hour and had become practically constant at the end of the second hour. The maximum temperature reached during a test was 370 deg. F. The mechanical efficiencies averaged 96 at the start and had become practically constant at end of an hour.

The average maximum efficiency for the tests shown was 98.7 while the absolute maximum was 98.9. This is a power loss of 1.1 or 0.55 hp. for a 50 hp. load on the transmission. Properly constructed and properly lubricated, the automobile transmission is a very efficient unit.

Where the wear had been very great, the mechanical efficiencies rose gradually and fell off shortly before the end of the test, but did not give any marked indication of the wear, as is shown by the rise in oil temperatures which were practically without exception proportional to the amount of wear.

Considering that at this speed the tooth picks up its load more in the nature of an impact blow, especially when slightly worn, we have another interpretation of the tests in the order the load is transmitted to each gear of the train in the table following.

From a careful study of these figures and curves, which are representative of the tests we are making on steels

Fig. 10—Oil temperature and efficiency of transmission

Order of Gear in Gear Train	Number of Teeth in Gear	Speed in R.P.M.	Pitch Line Velocity, Feet per Minute	Load at Pitch Line, Lb.	Load in Lb. per inch of face (assuming 1 1/2" face)	Total Number of Impacts on each Tooth
1	15	1500	982	1680	2986.66	540,000
2	27	833.3	982	1680	2986.66	300,000
3	22	833.3	800	2063	3667.55	300,000
4	20	917	800	2063	3667.55	330,120

for gears, we would recommend for oil treating, steel with a minimum of 0.45 carbon, that is capable of treatment giving a scleroscope hardness of 75 or over without brittleness and is as clean as it is commercially practical to make it; specification limits should be close enough to insure uniform results from a standard heat treatment.

## Advertising in South America

**A**N observer of South American conditions had occasion recently to remark that the advertisements in newspapers and magazines of that country lacked any distinctive style, and, in fact, poor styles predominate.

For the most part, he said, the advertisements are mere announcements that merchandise has arrived by such and such a ship. Or they are translations of exotic advertisements.

There is need for a distinctive style of advertising for South America; a racial style; something that smacks of the soil; a style of advertising that will be as effective with the South Americans as certain national advertising campaigns have been in the United States.

There are two main sources from which racy South American advertisements may be developed. The first is to be found in the literature and history of Spain and Portugal and in the literature and history of Spanish and Portuguese-speaking America.

The man who is to write South American advertisements that pull should study "Don Imjate" as the Pilgrim Fathers studied the Bible. In "Dom Imjate" may perhaps be found the subtle thread that will give the clew to Spanish character. In the *Lusiadas* of Camoens, the epic poem of Portugal, may be found many a side light on Portuguese character. In the history and literature of Brazil, Argentina, Chile, Peru, Colombia and Venezuela there is reflected, as in a mirror, the changes

Spanish and Portuguese character has undergone in the New World. The advertising man should catch these characteristics from their history and literature and make his propaganda appeal to them.

The other source from which aid may be obtained in the creation of an original style of advertising for South America, is in the study of modern business science as expressed by Spanish writers. These are now appearing in Spanish and are widely read in South America. These publications, in many cases are adaptations of works issued in the United States. But they are not mere translations. They are transpositions and express the Spanish psychology.

The export departments of our manufacturers should have these books in their export library. A careful study of them by export advertising managers and export advertising managers' assistants will be a rather powerful influence in the creation of a proper expression for South American advertising.

A masterful dominating style of advertising for South America that has the touch of genius about it would aid American manufacturers as much as anything else in keeping their place in the trade of the Southern continent.

**T**HE import duties on automobiles entering Sweden have been increased 100 per cent for the period from June 6, 1921, to July 1, 1922.

# Copper Tube Extrusion and the Manufacture of Radiator Cores

How seamless tubes are formed from solid stock by cold extrusion, shaped with hex ends and baffles, tested under pressure and finally assembled and soldered into complete radiator cores. An apparatus for determining the relative efficiency of various types of cores is also described.

By Herbert Chase

**T**HE advantage of seamless tube for use in radiator construction has long been appreciated, but the expense involved in making a radiator of the honey-comb type from such tube has until recently been too great for such radiators to be extensively used in this country, although some are used on European cars. It is difficult to make a thin walled seamless copper tube except by rather expensive drawing processes unless cold extrusion methods are employed, and this process has only recently been perfected. It was used extensively during the war for the production of tubes for cartridge shells, but has recently been adapted to the production of tubes of extremely thin walls well suited for use in manufacture of radiator cores. The process employed for making tubes and complete cores here described has been developed by the United States Cartridge Company, which is now producing both tubes and assembled cores in large quantities.

The material used for making the extruded tubes is practically pure copper. The process starts with solid cylindrical pieces of copper about  $\frac{1}{2}$  in. in diameter by  $\frac{5}{8}$  in. in length. These pieces are either punched from rolled copper sheets or cut from round bars. In the first operation a punch is forced into the cylindrical piece of copper so that the latter is rendered cup-shaped with rather thick walls and bottom. A second similar operation converts the cup into a thick walled tube or hollow cylinder with one end open and the other closed in whole or in part by a very thin flash. These two operations are performed in ordinary punch presses, the cylinders or cups being fed

to them from a revolving table similar to that used in connection with the extrusion press (see Fig. 2) on which the next operation is performed.

After the hollow cylindrical pieces are formed they are conveyed to the extrusion press, the feed side of which is shown in Fig. 2. The cylinders are there placed on a revolving table from which they are fed by the star-shaped wheel shown at the left of the cut. Each press carries two dies and two punches. The dies are stationary, but the punches are carried on transverse reciprocating slides, A and B. When A is at its inner position the punch which it carries is directly over the center of the die which it enters on the downstroke of the press. At the same instant the punch carried by slide B is in its outer position and is picking up from the revolving table one of the hollow cylinders of copper. On the upstroke of the press slide B and the punch attached to it move to their inner position, the punch carrying with it the copper cylinder which it has just picked up. At the same time slide A moves to its outer position and on the downstroke picks up another cylinder. On the same downstroke the punch on slide B moves downward, forcing the copper cylinder into the die. The punch then becomes a piston which upon further downward motion forces the copper through the annular opening between the lower end of the punch and the hole in the lower portion of the die. Since the shank of the punch fits the die closely the copper is positively forced out through the annular opening and comes out in the form of a straight tube about  $9\frac{1}{2}$  in. long and having a wall thickness of 0.005 to 0.006 of an inch. Since the

Fig. 1—(Left)—The extrusion die and punch. The copper cylinder is formed into the thin walled tube,  $9\frac{1}{2}$  in. long in a single operation lasting  $\frac{1}{40}$  part of a second. A sectional view of the punch and die is shown at the right

Fig. 2—The feed side of the extrusion press. The punch on slide A has just picked up a copper cylinder and is about to force it through the extruding die, while the punch carried by slide B is about to advance and pick up from the revolving feed table another cylinder which on the next down stroke of the press it will extrude from the second die. Fig. 3—Delivery side of the extrusion press. Tubes drop from the dies onto the endless belt and are discharged into boxes. Fig. 4—The high speed saws which cut the tubes to the desired length as they pass around the slotted drum. Fig. 5—The combined annealing and forming machine. This machine has a capacity of 250 tubes per min. Fig. 6—The machine which tests the tubes under 15 lbs. air pressure and automatically rejects any which leak

Fig. 7—Steps in the repair operation. At the left part of core with damaged tubes removed. Center—New tubes inserted. Right—New tubes being soldered in place

metal is heated only a few degrees during the extrusion the tubes are hard when discharged from the dies.

The extrusion process is best appreciated by reference to Fig. 1, which shows a punch and die, two of the copper cylinders, and one of the extruded tubes, as well as a sectional view through the punch and the die. During the time that the copper is flowing through the annular opening between the punch and the die the punch moves only  $\frac{5}{8}$  of an inch. This it does in  $\frac{1}{40}$  part of a second. The capacity of each press is 120 tubes per minute. Since the tubes have an average length of  $9\frac{1}{2}$  in. the machine produces approximately 100 ft. of tube per minute. Should the punch tend to move slightly out of its true central position in the die the greater friction of the metal passing through the narrower side of the annular space will deflect it centrally and thus maintain a uniform wall thickness. As the hole in the die or the punch itself wears the wall thickness will change slightly. The wall thickness is permitted to increase from 0.0055 to 0.0065 in., after which the punch or die bushing or both are renewed.

A continuous stream of lard oil is allowed to flow on the die, the oil being collected, passed through a centrifugal separator to remove metal particles, and returned to the extrusion machine. The press used is of the conventional crank type built by E. W. Bliss & Co.

As the tubes drop from the die they fall on an endless belt, as shown in Fig. 3, and are discharged into boxes provided for the purpose. They are then washed free of lard oil and are conveyed to the high speed sawing machine shown in Fig. 4. Here they are fed onto a slowly revolving, slotted drum. As the tubes fall into the slots on the drum an air-stream, issuing at high velocity from a nozzle near one end of the drum, moves them parallel to the axis of the drum against stop, after which they pass under the straps shown in cut and are sawed to the desired length.

The tubes are then ready to be fed to another machine, on which the hex ends are formed and the sides indented to give the desired baffling action. This machine is shown in Fig. 5. It performs the double function of annealing the ends of the tubes and of forming them to the desired shape. The annealing must be done in such a way as to soften only the ends of the tubes, while the intermediate portion remains hard, partly because the tube may be distorted in the dies if it is made soft over its entire length. It will be noted from the cut that the tubes are fed by hand into a slotted drum quite similar to that used in the sawing machine. As they travel around with the drum the ends of the tubes pass over a series of gas flames so adjusted as to anneal the ends of the tubes. They are then discharged into a slide and as they pass through the slide to the forming dies they are cooled by a stream of water. The forming dies are made in five parts. Two of these are punches of hexagonal sections but with rounded ends.

The punches are moved parallel to the axis of the tubes, being carried by guides and reciprocated in a horizontal plane by the cranks and connecting rods shown at each end of the forming head. The other three parts of the die are so arranged as to make indentations on the side walls of the tubes at the same time that the punches are forming the hexagonal ends. As the tubes drop from the dies they fall by gravity into suitable containers in which they are conveyed either to the assembly benches where the complete cores are built up or to a testing machine in which defective tubes are rejected.

All tubes which are shipped to radiator manufacturers to be built up into cores or to repair stations for use in radiator repair work are tested in a special machine shown in Fig. 6. The carrying element of this machine is a slotted drum which rotates slowly and into which the tubes are fed by hand. As the drum rotates a wheel carrying a series of cylinders with rubber headed plungers moves with it. At the proper angular position air is admitted successively to each of the cylinders, forcing the plunger against the end of the tube and the tube in turn against a rubber gasket at its other end, thus sealing the tube. The tube is filled with air through a hole in the plunger. Air is then shut off and the tube is gripped as long as it does not leak. Should there be a leak in the tube the pressure within it and the corresponding cylinder drops and the plunger lets go, rejecting the tube. If the tube does not leak it is carried further around and mechanically disengaged, dropping into another container. Following this testing operation the tubes are ready for shipment.

Tubes which are to be assembled into complete cores at the plant are not put through this automatic testing process, but are tested after assembly and dipping; that is, the entire core is then tested under air pressure and if any tubes are found to leak these are easily and quickly removed and replaced.

At the core assembly benches girls are employed to stack the tubes by hand, the latter being quickly placed in a proper position to form a true honeycomb. During this operation tubes which may have defective ends or are otherwise seen to be defective are rejected.

In the flat tube or ribbon type of honeycomb radiator individual tubes are continuous from top to bottom, so that there can be no flow of water across the radiator from side to side. With the individual tubular type of radiator the water can flow either vertically or horizontally, consequently, it is necessary to supply sheet metal side members for the vertical core. This is done by using a piece of crimped copper having a width equal to the length of the tubes and so formed as to fit the side of the honeycomb section. This member is formed by simply running a sheet of copper of the desired width through crimping rolls having teeth of half hexagonal section. When the

core is assembled a crimped strip is placed at each side of the core between the outer and the second row of tubes. With this construction the outer row of tubes, which is usually hidden behind the casing of the radiator, does not come in direct contact with the water but acts as indirect cooling surface. The tubes outside the crimped sheet can be slightly flattened or otherwise distorted without injury to the rest of the core if the core itself does not exactly fit the casing. They also tend to prevent injury in transit.

After the core tubes are assembled they are clamped in a wooden frame and are conveyed to the shipping room, where the frame with the tubes is laid on a face-plate to bring the ends of the tubes into a true plane.

The ends of the honeycomb core are then dipped in a special soldering flux which is said not to change strength with use. The entire length of the tube is not treated with flux, the depth of dipping being determined by adjustable screw stops on the frame. The bath of solder, which is arranged in a tank adjacent to the flux bath, is kept at the desired temperature (as measured by a thermo-couple) by a gas flame. The honeycomb is dipped into the solder bath in precisely the same way as it is dipped in the flux, only the ends of the tubes coming in contact with the solder. First one side and then the other side of the core is dipped. The core is shaken to remove excess solder immediately after dipping each face.

Following the dipping operation the cores are thoroughly washed to remove all traces of flux. They are then ready for the top and bottom plates to be attached. These may if desired be of a temporary nature suitable only for testing purposes. In any case each core is tested under an air pressure of 15 to 20 lb. per sq. in. and if any leak is found a new tube is easily inserted.

In order to demonstrate the facility with which damaged tubes can be replaced in doing repair work, the writer, who recently visited the plant, was requested to deliberately damage a core with a hammer. The tubes within a circle of about two inches were thus broken and the core turned over to a repairman. All of the broken tubes, twenty-four in number, were removed in 6½ minutes. This was done by inserting in each end of the tube a soldering iron with hexagonal ends. Then, tapping the tube gently until it could be easily pulled out with pliers. The broken tubes were then replaced by new ones, a soldering iron being used to apply enough solder to hold the first few in place. The last four or five tubes were easily tapped in place by using a hammer, after which a small gas torch and an iron was used to apply solder at the joints between new tubes and between the new and old tubes. The entire repair job

was completed in approximately 24 minutes.

In order to make the most efficient radiator possible with the construction employed it was necessary to determine what form of baffling produced best results. The experimental testing apparatus shown in Fig. 8 was used for this purpose as well as to compare cores made by the process described with those of other makes. By use of the baffles now employed it has been found possible to increase the cooling efficiency of the radiator over one without baffles approximately 25 per cent at air speeds up to about 60 miles per hour.

The testing apparatus is constructed as follows: A motor-driven blower is mounted on top of a closed air chamber into which the blower discharges. The only outlet to this chamber is through an air tunnel 1 ft. square in section and 10 ft. long. The joint between the tunnel and the air chamber is made by a rubber band in order to prevent vibrations of the blower and blower motor from causing the radiator to vibrate, since this was found to have an appreciable effect upon the results of the test. The outer end of the air tunnel is fitted with a shallow box with a gasket against which the sample core for testing is placed. When the core is in place it is connected to the water circulating pump and a gravity tank by rubber hose as shown in the diagram. Water drawn from the tank below the radiator is circulated through a gas water heater and discharged into a tank above the radiator. From this tank it flows into the radiator through a valve and flexible hose. From the bottom of the radiator water flows into another tank through another regulating valve.

A small float is placed in the upper chamber of the radiator, and the water circulation is so regulated by the valves that this float remains at a constant level. The thermometers are arranged to measure the temperature of the water entering and leaving the core and of air passing into and out of the core. A Pitot tube is arranged to measure the air velocity by the use of an inclined anemometer. After an equilibrium condition has been established the rate of flow is determined by measuring the time required for a given weight of water to flow into the tank on the platform scales. The air velocity through the tunnel is varied by adjusting the slide which covers a part of the blower inlet. The apparatus is not intended to exactly duplicate service conditions, but is said to give true comparative results.

# Relief Methods Recommended at Unemployment Conference

Emergency measures looking to the solving of the present situation were adopted, but a program designed to prevent a recurrence of conditions as they are was suggested by the delegates. Adjustment of railway rates and completion of tax and tariff legislation were among important proposals.

**P**RESIDENT HARDING'S conference on unemployment has resulted in recommendations affecting practically all the major industries of the country. If they were put into effect to the extent that is obviously possible, they would go a long way toward permanent relief of the situation. The closing of the conference did not result in a flare of trumpets and the announcement that within a week the United States Government would be in a position to see to it that every unemployed man would have work, but rather there was a quiet agreement among the delegates as to the measures to be taken, and how they should go about the important task of putting the idle to work.

No big concerted action was agreed upon, but every city in the United States was allotted the task of solving its own situation along the lines developed at the conference. Vital matters were brought to the attention of Congress so that the members of that body could see how the measures they are deliberating upon would affect the situation, and the need for quick action was impressed upon them.

Actual, immediate and tangible results from the conference can only be accomplished through the co-operation of various cities and civic bodies throughout the country, as well as the co-operation of all industry. Secretary Hoover of the Department of Commerce, and chairman of the conference, pretty well expressed this feeling when, in his closing speech, he said in connection with the recommendations offered:

"You have laid out a plan. The plan has been willingly accepted by a large section of the country, and you have erected the machinery to pursue that work, and we will see if we cannot get through this crisis without calling on the funds in the public purse for support and subsistence of our unemployed. Whether or not we succeed in that will depend greatly upon the co-ordination and co-operation that we can figure from industries and civic bodies of the United States. That this is a problem for voluntary organization is consonant with American spirit and American institutions. If we cannot secure its solution in that direction, we shall have made a distinct step backward in the progress of this country. It is, therefore, vital that you who return for a term to your own sections of the United States should insist, in season and out of season, that this is a problem that rests upon the voluntary and neighborly action of the American people."

## Recommendations for Permanent Relief

Many of the recommendations submitted to the conference by the various committees were of particular interest to the automotive industry, as well as to the country as a whole. Increased production, naturally, was one of the most proposed methods of

alleviating unemployment, and just as naturally, increased production cannot be accomplished unless certain other things have been accomplished first. The general recommendations of the entire conference for measures looking to permanent recovery of employment seemed to strike at the bottom of the production situation.

There were eight of these recommendations, as follows:

1. Readjustment of railway rates.
2. Speedy completion of the tax bill.
3. Definite settlement of tariff legislation.
4. Settlement of financial relationships between the government and railways.
5. Limitation of world armament.
6. Minimizing fluctuations in foreign exchange.
7. Elimination of waste and a program of more regular employment in seasonal and intermittent industries.
8. Speedy adjustment of the inequalities in deflation.

All these subjects have been discussed at great length in connection with almost every problem that comes up. They affect not only the unemployment situation, but many other situations, and many of the others revert back to unemployment. It is a sort of endless chain effect, and despite the temporary measures urged by the conference, such as road building, home building and other projects designed to meet the emergency, little can be done toward permanent recovery of employment until these vital issues have been settled one way or another. Opinions may differ, it is true, as to what form the tariff bill should take, but either its enactment in any form or its definite failure of enactment, would prove a helpful factor, for then industry would know what to expect and prepare to meet conditions. It is the uncertainty of the thing that retards progress.

The readjustment of railway rates is recognized as a necessary step toward readjustment of conditions. The conference proposed that the rates be adjusted to a fairer basis of the relative value of commodities, and asked that special consideration be shown in fixing the rates upon primary commodities. This was in line with one of the recommendations of the agricultural committee, which insisted that the rates both on farm produce and on goods shipped to the farmer were entirely too high. The conference, however, did not overlook the fact that the financial stability of the roads should be safeguarded. Certainly lowering of railway rates would have the effect of stimulating production in that the purchase price would be lowered and sales would increase.

The tax and tariff measures are those which affect every industry and individual in the country. The con-

ference did not specify what tariff should be enacted, neither did it specify the tax rate, except to urge reduction of taxes, but it did point out that the measures must have something done to them in order to speed up a return to prosperity. Industry cannot prosper when it has no clear vision into the future. Until the clouds are removed from the political horizon there can be no rapid speeding up of production. Clouds are pretty good forecasters of a storm, and the good seaman will attempt to navigate around that storm. If it is blown away then so much the better, but if it is to come all industry is hoping that it will come soon, for afterward the skies will be clear and smoother sailing will lie ahead.

Aside from a lowering of their rates, the railways could perform other necessary duties that would tend to lessen the number of unemployed for all time. The present status of financial relationships between the railroads and the Government is such as not to inspire any too great confidence in the former's future. A settlement of these difficulties would obviously bring about increased railway employment and stimulate general employment. Immediate settlement of these relationships would provide immediate relief in that maintenance and betterment work could proceed, and when enlarged business comes the railways would be prepared to handle it.

#### Armament and Foreign Exchange

The prosperity of the United States depends not alone upon its own prosperity, but, especially since the war, upon the prosperity of other nations. A decrease in the tax burden of other nations would release more money from those countries for the purchase of American goods, and, conversely, a decrease of America's tax burden would allow the purchase of more goods abroad. One way of decreasing these tax burdens would be the reduction of world armament. Besides the economic benefits to be derived from such a move, there is the human side. Peace and tranquillity would be more nearly assured, and, after all, the human factor has a fundamental effect upon economic trends.

The decrease in taxes of all nations, and the consequent buying and selling between countries, would also have the effect of reducing the fluctuations in foreign exchange, another recommendation by the conference. The Committee on Foreign Trade, in its report to the conference, went into this situation quite thoroughly and pointed out some of the difficulties facing American business as a result of the fluctuations and suggested a few remedies. As the conditions stand, no merchant can well afford to take the risks of shipping his goods to a foreign nation with the knowledge that he cannot determine the delivery cost of any international shipment. The Committee on Foreign Trade pointed out as causes of the fluctuations the unbalanced budgets of many foreign countries, and the "unregulated demands of the German Government for foreign currencies in order to complete reparation payments."

This committee, in offering a remedy for these conditions, called on Congress to enable the administration to deal with the funding of foreign debts owed to the United States Government in such a way as to avoid injury to our foreign trade and our employment. It was also urged that the United States be effective in the deliberations of the Reparations Commission and other agencies, so that its influence may be exerted toward a reasonable control of the present unregulated payment of reparations by Germany.

A definite program of action that will lead to elimination of waste and more regular employment in seasonal and intermittent industries, in order that the drain upon

capital may be lessened and the annual income of the workers may be increased, was another recommendation of the conference. The coal industry was pointed to as one into which seasonal employment enters, and the conference urged measures of relief taken in that industry at once. The Committee on Mines, in its report, suggested that railroads maintain at all times along their lines a supply of bituminous coal sufficient to last for five months. This suggestion should not apply only to the railroads, but to every other industry that uses coal as well.

Finally, the conference recommended a speedy adjustment of the inequalities in deflation. In comparing present price levels of various commodities and services with those of the pre-war period it was shown that agriculture has reached an unduly low plane, while transportation, coal and some branches of the construction industries are of the highest. An entire disproportion between the price of the primary commodities and the ultimate retail price was also declared to exist, and the reasons given for these increases were declared to be increased costs of transportation, enlarged profits, taxes, interest, labor and other charges.

"If the buying power of the different elements of the community is to be restored," said the recommendation, "then these levels must reach nearer a relative plane. For example, the farmer cannot resume his full consuming power and thus give increased employment to the other industries until either his prices increase or until more of the other products and services come into fair balance with his commodities and therefore the reach of his income."

All these recommendations may seem far away from the man who wanders the streets in search of a job. They appear, on the surface, to be connected with matters pertaining to government and politics, and, in fact, they are. These recommendations were made, however, after a careful study of the unemployment situation, and they were framed to correct the fundamental current evils. As far as being emergency measures is concerned they probably do not amount to much, but other methods were undertaken to care for the immediate needs. The methods discussed go farther than the present. They look to the establishment of permanent good business and prevention of a recurrence of present conditions.

#### The Business Cycle

The conference went to the extent of recommending an exhaustive investigation into the causes and remedies of periodic business depressions. Business depressions of other years were discussed in a report along this line, and it was declared that the long succession of business crises does not prove that the problem of controlling the business cycle is a hopeless one.

"The business cycle," said this report, "is marked by peak periods of boom between valleys of depression and unemployment. The peak periods of boom are times of speculation, over-expansion, extravagance in living, relaxation in effort, wasteful expenditure in industry and commerce, with consequent destruction of capital. The valleys are marked by business stagnation, unemployment and suffering. Both of these extremes are vicious and the vices of one beget the vices of the other. It is the wastes, the miscalculations and the maladjustments grown rampant during booms that make inevitable the painful process of liquidation. The most hopeful way to check the losses and misery of depression is, therefore, to check the feverish extremes of 'prosperity.'"

The best time to act is at a fairly early stage in the growth of the boom."

This report went on to recommend that industry put aside financial reserves, to be provided in times of prosperity, for the deliberate purpose of improvement and expansion in times of depression. Such action, the report said, would not only lessen the depth of the valleys in the business cycle, but would also lower the heights of the peaks.

The emergency measures adopted by the conference are pretty generally known. As was pointed out, each community is given the burden to bear so far as the situation affects that community. Exchanges are being organized whereby a city with a shortage of labor can immediately be informed as to where the class of labor it desires is available. Employment agencies are busily engaged in securing and compiling information on employment opportunities throughout the country. If ship builders and operators are carrying out the recommendations of their committee there has been an elimination

of overtime work for stevedores and men engaged in allied work. Rather there has sprung up a split-time basis in order to give jobs to more men. The committee urged that the United States Shipping Board expedite the breaking up of wooden tonnage on hand, and using the material for constructive purposes. Overhauling of ships likely to be used soon was another idea urged upon the marine industry. The Committee on Public Roads urged more activity in road building, and there were many other of these committee reports that offered emergency relief. These measures are being put into effect now, and in due time their result will be felt. But with all the emergency measures the result will be but temporary. Road work cannot go on forever, neither can the breaking up of wooden ships, and sooner or later men working as stevedores, or as anything else, must have full-time work. This can be brought about only by the adoption of a permanent policy that will stabilize industry in general and consequently stabilize employment.

## Postal Rates to Pan-American Countries Will Be Lowered

THE lowering of postal rates and improvement of the parcel post to foreign countries is a subject of pressing importance to exporters and automotive manufacturers engaged in overseas trade. Consequently, the action of the recent Pan-American Postal Convention at Buenos Aires is fraught with promise for the future course of commercial relations between the countries of Pan-America.

In substance the convention's action will have as its result the lowering of postage rates from the United States to all countries of Pan-America to the domestic rate of two cents. This rate is now in effect to Mexico, Cuba, Dominican Republic, Porto Rico, Nicaragua, Honduras, Panama and the Canal Zone, Colombia, Peru and Bolivia. The Pan-American convention will lower it to all countries, and after it goes into effect the same rate will apply to Argentina, Brazil, Chile, Uruguay, Venezuela and elsewhere as for letter transmission in continental United States.

The simplification and betterment of the parcel post is perhaps of even greater import. At present it is almost impossible to send shipments of advertising or sales literature, catalogs, small parts and accessories to the various countries of Latin-America by parcel post. The regulations differ in each country. Special charges of various kinds, with numerous penalties for non-compliance with vexatious and little-understood rules, pile up on the receiver to such an extent that the parcel post can seldom be used.

The Buenos Aires convention eliminated all these vexatious regulations and adopted a single system that will be used in each country. In the words of O. K. Davis, who headed the American delegation, the result will be to exchange nineteen systems for one. The Pan-American limit for parcel post packages will be 10 kilos (22 lb.) except to a few interior countries in which special conditions limit the packages to half that size. This limitation does not pertain to the larger countries, such as Argentina, Brazil, Chile and Peru. Furthermore, all charges against the receiver of the package, except custom duties that are payable in the country of destination, are wiped out and replaced by a single charge of ten cents American gold assessed against the sender of the package. This single provision is declared to be one of the most important contributions of recent

months to the promotion of closer trade relations between North and South America. It will eliminate the costly delays, penalties, charges, etc., that to-day pile up in some countries against the receiver and which make it impossible for the American shipper to use the system.

One point on which the convention was unable to act concerned the filing of consular invoices with parcel post packages and one slight reservation was made by Argentina against the convention because of its custom laws. Therefore, the matter of consular invoices must remain as at present, because any change in it concerns the custom laws of each country and, therefore, did not come within the province of the Buenos Aires deliberations. It has been proposed that a custom conference be held to take up this point.

The convention was unanimously agreed upon the proposals, with the reservations enumerated, and they will go into effect generally on Jan. 1, 1923. This delay was caused by the fact that the Mexican congress will be unable to act upon ratification before the latter part of next year, as it does not have another meeting before that time. However, the agreement provides that the provisions may be put into effect at any date prior to that time by countries ratifying them. This leads to the hope that its provisions will become effective in some sections shortly.

In commenting upon the convention, Mr. Davis declared that the results would go a long way in furthering Pan-American solidarity, as the rates provided are much lower than those prevailing between American countries and Europe. In fact, the American dollar was made the standard for the convention.

**A** NAPHTHALINE engine for stationary purposes is being manufactured by the Deutz Gasmotorenfabrik of Germany. The naphthaline is kept in the liquid state by means of steam generated by the exhaust gases, both the naphthaline container and the feed passage being surrounded with a steam jacket. Naphthaline at present costs only about half as much as benzol, the conventional liquid hydro-carbon fuel in Germany, on the weight basis. The engine must be warmed up with benzol or illuminating gas, and in the case of a 20-hp. engine it is necessary to run 15 minutes on this auxiliary fuel.

# The Argentine Automotive Market

Here is the most recent and authoritative summary of the automotive situation that has come to the United States. Internal conditions in Argentina are fundamentally sound. First nine months of 1921 were dark ones, but a trade revival has begun. The reasons are discussed in detail.

By M. T. Meadows\*

BUENOS AIRES, ARGENTINA, Oct. 1.

**T**HE internal conditions of Argentina are to-day fundamentally sound. This, despite the fact that the country has undergone during the past ten months a period of business depression more serious than any experienced since 1914. The causes of this depression have been, broadly speaking, the decline in the values of Argentine foodstuffs and raw materials in the world's consuming markets with the aggravating circumstances of a restricted demand for these products, even at low prices.

The picture as painted during the first nine months of 1921 is a dark one. Happily its colors are now brighter. In fact, even the more pessimistic observers are granting that the worst of the storm has blown over and that an improvement may be confidently expected.

A month ago many business men thoroughly familiar with trade conditions in Argentina predicted a trade revival contingent upon three things:

First—General rains throughout the country.

Second—The conclusion of negotiations for a \$50,000,000 loan.

Third—The granting by the National Bank of a two-year moratorium to its clients who had obtained credits on cattle mortgage liens.

During September the menace threatening Argentina with a disastrous crop and cattle failure, in the form of the most serious drought experienced by the country in the past decade, was dispelled by heavy rains which benefited all sections of the country. The \$50,000,000 loan was secured and the last-named condition for a return to more prosperous times seems to be well on its way toward fulfillment.

It is true that the volume of Argentine grain exports during 1921 were vastly inferior to those effected during same period of the previous year. However, grain prices have been well sustained and farmers have received ample remuneration for their produce. Cattle prices during September have shown an increasing tendency upward. The effects of this steadiness in the meat market are already being noticed in the readiness of ranchers and interior merchants to purchase more liberally those commodities required by them. Another factor which is considered as most favorable is the decided firmness in the prices of hides which, of course, is having a marked influence in the betterment of the live stock business.

Fortunately, a growing demand for all grades of Argentine wool is to-day becoming more evident. Buyers are to be found not only for the finer wools, which met with some sale even in the period of the depression, but also for the enormous stocks of coarse wool which some

months ago could not be disposed of at any price. These circumstances, together with the prospects of good crops, should mean that the Argentine can soon resume the purchase of American cars on a scale which, even though not commensurate with the demand during the past four years, will be sufficiently large to supply normal post-war requirements.

On Jan. 1, there were 3,500 automobiles held in the bonded warehouses of Buenos Aires. This number did not include Ford cars which are brought into the country as spares and assembled here. The liquidation of this stock during the present year has been slow but steady. By March 1, 2,003 cars were still in the custom-house. To-day the number in the custom-house is considerably less than 1,000. It is well to add that of this number more than 500 have already been paid for by the importers. Beyond a doubt, the end of the present year will see a final liquidation of these cars and certainly before the end of the spring and summer selling season now ushered in these vehicles will have been marketed and importers will be forced to place new orders.

Even a cursory investigation will demonstrate to what extent American cars predominate in the Argentine market. It is true, of course, that prior to 1914 European automobiles, especially French makes, were the only ones finding ready acceptance. The universal use of automobiles in Argentina is, however, entirely due to the popularity of the low-priced American vehicles. Not only in the Argentine cities, but even in the most distant hamlets and rural districts, Fords, Chevrolets, Dodges, Maxwells, Buicks, etc., are to be found in abundance. Higher priced cars are usually owned in the cities and larger towns, but Packards, Cadillacs, Hudsons, Hupmobiles, Studebakers, etc., are to be found here much in the same relation to the total number of automobiles as in the United States.

At the present time there are no statistics available giving the number of automobiles in actual use in Argentina. An effort is being made by the local Automobile Chamber of Commerce to take an automobile census, but this information will not be ready for publication before the end of the present year.

Automobile and tire importers estimate that from 70,000 to 80,000 cars are now being used in the republic. Of this number, approximately 55,000 are used outside of the larger cities. This plainly demonstrates the fact that ranchers and farmers are the heaviest buyers of automobiles. Buenos Aires is credited with approximately 15,000 cars in use within the city limits. Licensed taxicabs comprise about 6,500 of this number, with nearly 8,500 cars in the hands of private owners. The ready sale of the Ford is shown by the fact that more than 40,000 trucks have been sold in Argentina since 1914.

# New Commodity Divisions Will Give Industry Many Advantages

Reorganization of Bureau of Foreign and Domestic Commerce includes the formation of divisions that will function for automotive industry and rubber exporters as well. Collection and distribution of merchandising information as it is related to international trade will be chief task.

IT has been understood for some time that the Bureau of Foreign and Domestic Commerce was undergoing a general reorganization and that it would soon be equipped to handle the problems of American business in a more practical and constructive way than in the past. This reorganization has been completed to a large extent, and already the parts of the Bureau relating to automotive products are in a position to function efficiently. An analysis of the aims and possibilities of the reorganized Bureau indicates that a source of real aid to the manufacturer is being established which will help him in solving many practical business problems, especially those relating to international trade.

A general survey of the changes in the Bureau, together with a somewhat detailed discussion of the functions of the automotive division in particular, will make clear to manufacturers just what may be expected from the Bureau in the way of service, and how the facilities of the Bureau can be most efficiently utilized. The most striking development in the Bureau consists of the creation of fourteen new commodity divisions. The names of these fourteen divisions and of the men in charge are:

Agricultural Implements and Vehicles.....	George B. Bell
Automotive.....	Gordon Lee, Wm. I. Irvine
Electrical Goods and Machinery.....	Ruben A. Lundquist
Fuel.....	Henry C. Morris
Boots, Shoes and Leather.....	Arthur B. Butman
Lumber.....	Axel H. Oxholm
Foodstuffs .....	Edward G. Montgomery
Iron and Steel.....	W. S. Tower
Industrial Machinery.....	Walter H. Rastall
Rubber .....	Paul L. Palmerton
Textiles.....	Edward T. Pickard
Chemicals .....	(Open)
Paper .....	(Open)
Specialties .....	(Open)

These new commodity divisions are additional to the former geographic divisions, and are designed to render a distinctive service which has not previously been performed for American industry by the Bureau. The men appointed to take charge of the various commodity divisions have all been drawn from industry itself. They are men who have had practical experience in the industry which they represent and are thoroughly familiar with the requirements and problems of practical business.

It is the duty of these men to keep in the closest possible touch with the centers of the industries they serve by way of appropriate commercial organizations, trade papers, editors and individual manufacturers and merchants. They are charged with the responsibility of ascertaining the character of the information most urgently

needed by their particular industry. With this as a basis, it is their task to utilize the existing world-wide facilities of the Department of Commerce, consisting at present of over 600 foreign representatives in promptly obtaining the information desired.

Their long experience in a special knowledge of the peculiar problems connected with each industry should result, it is believed, in the rendering of reports which will be understood in their true significance by the American business men concerned. These men will also see to it that reports reaching the department from all sources are properly interpreted from an industrial standpoint and are immediately submitted to the points where they will do the most good.

The automotive division has already begun to function actively. The co-operation of the National Automobile Chamber of Commerce has been extended to it, and through that contact considerable mutual benefit will doubtless accrue. One of the chief interests of the automotive division at this time is to get manufacturers to tell their troubles to the division; to let the division have their opinions as to what service they believe can be rendered, and the best form of rendering that service.

There is a vast amount of information available from consuls, trade commissioners, and commercial attachés, which if properly interpreted and compiled, will be of infinite value to American manufacturers in connection with their international trade. The agent's reports in the past have frequently been useless because the consul was not thoroughly familiar with the information desired and the use to which it was to be put. The automotive division is taking definite steps to acquaint the agents in various parts of the world with a detailed analysis of the sort of information desired by American automotive manufacturers, and will consequently have at its disposal before long really worth-while commercial data.

## Analysis of Foreign Markets

It is expected that one of the members of the division will make an extended trip of several months shortly after the first of the year with the purpose of analyzing thoroughly, from the standpoint of American automotive selling, some specific foreign market. This survey will not be the usual seaport investigation consisting of general statements and hearsay data. It will be conducted with thoroughness and will be designed to reveal practical material of selling value. The man making the survey will go out with a complete knowledge of the marketing problems of the American automotive industry and will seek throughout the country the kind of specific trade information that would be desired from a personal representative of an individual manufacturer.

The first foreign market to be investigated in this manner will depend to a large extent upon the desires of the automotive manufacturers, but present indications are that China in particular, or the Far East in general, will be the first ground covered.

Efforts are being made to present statistical data to the automotive industry in such a way that it will be of practical value. The reclassification of automotive export statistics announced recently marks a definite step in advance. The reclassification as announced by AUTOMOTIVE INDUSTRIES, it will be recalled, affected cars, trucks, tires and aircraft. It showed that the American export statistics would be compiled and issued under the following classifications beginning with Jan. 1, 1922:

*Cars*

1. Under \$800.
2. Over \$800 and under \$2,000.
3. Over \$2,000.

*Trucks*

1. 1 ton and under.
2. 1¼ tons to 2½ tons inclusive.
3. Over 2½ tons.

*Tires*

1. Pneumatic casings for automobiles.
2. Other pneumatic casings.
3. Pneumatic tubes for automobiles.
4. Other pneumatic tubes.
5. Solid tires for automobiles and trucks.
6. Other solid tires.
7. Tire repair materials.

*Aircraft*

1. Airplanes and hydroplanes.
2. Other aircraft.

Comparing these classifications with the present one, it is readily evident that the export information available next year will be of far more selling value than it is now. These classifications, while perhaps not the last word so far as manufacturers' information is concerned, undoubtedly will reveal much information not now available and will enable American firms to analyze more intelligently the trade with various individual countries.

The handling of tractor statistics is another problem being discussed by the automotive and the agricultural section. A definite decision has not yet been reached in regard to the listing of tractor exports. There is some discussion as to whether tractors belong to the agricultural or automotive divisions. According to the present status, agricultural tractors will be listed in the agricultural machinery and implements section under the following heads:

1. Farm Tractors
  - a. Wheel
  - b. Track laying

Under the power generating machinery division will be listed the commercial tractors under this head:

Complete Tractors, Except Agricultural.

The inconsistency of this practice as regards tractors is evident from the standpoint of business needs and sales analysis. There is every likelihood that a better grouping will be determined before next year's program goes into effect.

These specific incidents are cited, however, to indicate the kind of problems with which the automotive division is concerned and to illustrate the practical efforts which are being made to render more effective existing potential services, to extend the service in many ways, and to enable the government bureau to function efficiently in co-operation with the automotive manufacturer.

The rubber division is also of special interest to automotive manufacturers since a large percentage of the material handled by this division relates to automobile and truck tires. This division is organized and functions as does the automotive and other sections, so that a few details of its work serve as typical examples of what it and the automotive division are doing.

### Purposes of Rubber Division

The first purpose of this division will be to give exporters information that will be complete and accurate on the world's markets for their products. Two representatives of the division, one of whom will be traveling at all times, will determine just what information is desired by the industry and the complete facilities of the bureau will be used to obtain the data required. At present all information on the rubber goods market that is available in the Bureau of Foreign and Domestic Commerce is being gathered and filed in the rubber division. All this data will be checked for inaccuracies and incompleteness and the field force of the bureau will be asked to supply missing information or verify that now on hand. It is also planned to have questionnaires constantly going to representatives of the United States in all territories and a return stream of information always coming into the division.

Dissemination of this information will be partly through "Commerce Reports," and partly through answers to correspondence from manufacturers inquiring about some particular phase of the industry. Present indications have pointed out the fact that "Commerce Reports" will not be able to print all the information received, and for this reason answers to special inquiries will form one of the major outlets for the distribution of information. Special bulletins will also be sent out to the industry that contain pertinent information that cannot await publication.

As in the past confidential information will be sent only to firms that are American owned and controlled. Special trade opportunities and importers' lists will be sent only to companies who have filed with the bureau a form showing this to be true. The list of companies thus qualifying will form what is known as the Exporters' Index, and admission to this index can be obtained by applying for and filling out Form 57 which will be supplied by the Rubber Division upon request. Indexed firms will be given the advantage of having specific trade opportunities automatically delivered to them instead of having them published under a special key number.

### Comprehensive Surveys Projected

As in the automotive division, collection and interpretation of statistics on the export trade will be a task of the division. Such statistics are now issued each month, but there are certain other channels, not now generally employed, through which the division will secure valuable information which will serve admirably as guides to better and greater markets. Certain markets, at times, will undergo unusually comprehensive surveys. This will usually be accomplished by putting a man from the division right in the country to be investigated. Rubber and motor journals from all over the world will be read and foreign competitors will be watched and reported upon.

The usefulness of the automotive and rubber divisions will depend largely upon the assistance given to them by the manufacturers and the extent to which manufacturers take advantage of the information which is being made available. The automotive section is among the first of the commodity divisions to begin to function at high efficiency and manufacturers are having opened to them a source of accurate and practical trade information that has not before been available.

# Patent Bureau Efficiency Will Aid Manufacturer

The Lampert measure now before Congress would increase the salaries of employees and officials in this important government office as well as provide for a large increase in the working force. One-fourth of patents applied for affect automobile industry. Bill would aid in other ways.

SOMEWHERE beneath the measures affecting the tariff, peace with Germany, taxes and disarmament there lies in Washington a bill designed to increase the salaries and working force of the patent office. Whether or not it will be acted upon or even discussed at the present session of Congress is somewhat problematical in view of the rush of important legislation that representatives and senators are facing, but if it does come to the fore before adjournment, manufacturers of automobiles and automotive equipment will be particularly interested in its fate. Just what this will mean to the manufacturer in automotive industries can be realized when it is known that fully 25 per cent of all patents now being issued pertain in one way or another to automobiles.

A similar bill, sponsored by Representative Nolan, was defeated at a recent session after every indication had been given that it would go through. When this measure first came up there was scarcely a dissenting voice heard. The road seemed clear for immediate passage, when suddenly a provision was added that caused those favoring the bill to immediately change their views and the measure was defeated. The reason ascribed for this almost over-night reversal of opinion was a section providing that government employees who had patentable ideas should turn those ideas over to the Federal Trade Commission; the government would secure a certain amount of the revenue from the patent and the employee the remainder. This section of the bill was, no doubt, intended to encourage scientific men to enter the government service, but an analysis of the measure by various industrial interests brought out a few interesting facts that, when they became known, practically caused the bill's defeat.

## The Objectionable Feature

It was pointed out that various government bureaus exist which are operated for the benefit of the taxpayer. The Bureau of Mines might be taken as an example, and a mine owner or his representative might write to this organization asking advice on some technical mining question. A government employee would be assigned to the case, solve the problem and send the answer to the mine owner. If the answer contained some original feature the bureau employee could patent the idea through the Federal Trade Commission, which in turn could bring action against the mine owner for an infringement of the patent rights.

It was this feature that caused the untimely death of the otherwise unobjectionable Nolan bill. The new measure, introduced by Representative Lampert, does not include this provision, but in substance its other provisions are similar to those in the original Nolan bill. The scale of annual salaries for various patent

office officials would be fixed under the new bill as follows:

Commissioner of Patents, \$6,000; first assistant commissioner, \$5,500; assistant commissioner, \$5,000; five examiners-in-chief, \$5,000 each; chief clerk, \$4,000; six law examiners, \$4,000 each; examiner of classification, \$4,200; two examiners of interference, \$3,900 each; examiner of trade-marks and designs, \$3,900; first assistant examiner of trade-marks and designs, \$3,000; forty-seven principal examiners, \$3,900 each; one hundred first assistants, \$3,300 each; thirty first assistants, \$3,100 each.

The schedule of salaries also includes many other assistant examiners, clerks and others at salaries ranging from \$2,900 to \$1,080 a year.

## Patent Bureau Operates at Profit

These salaries are practically the same as those provided for in the Nolan bill. It has been repeatedly pointed out in connection with the request for higher salaries that the patent office is one of the few, if not the only government department, that operates at a profit. It has done this since its inauguration, and those friendly toward the measure are confident that the increased salaries will be taken care of by revenue from the office. In fact, the salaries were figured on this basis.

The bill, if passed, will mean considerable to the manufacturer, for with an increased working force the long delays prevalent between the time a patent is filed and when the first action is secured should be eliminated. At the present time the patent office force is composed of a few conscientious men who are doing all within their power to maintain efficiency, but their power is limited by lack of funds and lack of help. It has been figured that of the vast number of cases taken to the office to be examined, the examiner does not have an average of a full day for each case. Naturally this does not tend to increase efficiency.

## The Present Salaries

As to whether or not the patent office officials and employees are deserving of an increase in salary it should be borne in mind that the last increase to this department was granted in 1907. The only increase prior to that time was back in 1840 or '45. At that time patent office officials received the same salaries as congressmen. The present scale of salaries is as follows:

Commissioner of Patents, \$5,000; first assistant commissioner, \$4,500; second assistant commissioner, \$3,500; three examiners-in-chief, \$3,500 each; chief clerk, \$3,000; two law examiners, \$2,750; examiner of interference, \$2,700; examiner of trade-marks and design, \$2,700; forty-three principal examiners, \$2,700 each; sixty-three first assistants, \$2,400 each.

There are, of course, many other assistant examiners and clerks who receive salaries below \$2,000 a year. A part of the increase in the working force is shown by a comparison of the two tables of salaries. There are also additions in the clerical and examining forces provided for under the Lampert measure.

There is one thing that may stand in the way of passage of this measure. That is the fact that a federal commission has been working for a year or more on a general revision of government employees' salaries, and some congressmen may feel that this revision, when it is completed and acted upon, will take care of all departments alike, and dealing with one separate department would be somewhat partial. It is probably true that other departments are as deserving of increases as are the employees in the patent office.

Under the present system, or lack of system, of computing government employees' salaries a highly trained engineer in one bureau may be receiving an adequate salary, while on the next floor, in another department, there might be another engineer, with the same training, the same ability and doing equally important work, who receives half the salary of the first. The commission is working to overcome this discrepancy.

#### Other Important Provisions

But there are other portions of the patent bill that deserve consideration. The fact that it increases the working force of the department is enough in itself to make it a worth-while measure. Various provisions are attached to it, however, some of them merely being of a minor nature, but one or two are of sufficient importance to be commented upon.

One feature of the measure provides that when court action is begun in any patent case in the various courts throughout the country, the clerk of the court shall file notice of such action in the patent bureau within one month from the time such action is begun. This is not done at present, and parties interested in buying patents often go to the patent office to look up data on the case and remain uninformed of the fact that legal action is being taken for some cause or another. The provision states that the patent commissioner must have notice of such litigation filed with the original patent papers.

In the patent law now in operation there is a section providing that holders of patents who bring suit to recover alleged losses from the misuse of the patent must show definitely the amount involved and present other information that in most cases would be extremely difficult to secure.

A clause in the Lampert measure makes a new provision in this respect. The various federal courts are given the power to grant injunctions to prevent the violation of any right secured by patent, and, upon a decree being rendered in any such case for an infringement, "the complainant shall be entitled to recover, in addition to the profits to be accounted for by the defendant, the damages the complainant has sustained thereby." The measure further provides that "if on the proofs it shall appear that the complainant has suffered damage from the infringement or that the defendant has realized profits therefrom to which the complainant is justly entitled, but that such damages or profits are not susceptible of calculation and determination with reasonable certainty," the court may accept expert testimony on the subject and determine the amount the defendant has to pay.

This, of course, is a protective measure for the patentee and one to which he is entitled. Another protection offered the inventor is the barring of attorneys or agents who are incompetent or dishonest from having

dealings with the patent office. The Commissioner of Patents is given the power to prescribe rules and regulations governing the recognition of such agents, and to require them to show that they possess the qualifications necessary to render their clients valuable service.

#### Fees Slightly Increased

The bill would also change the rates for patent fees as follows:

	Present fees	New fees provided
Due with application.....	\$15	\$20
Upon allowance of patent.....	20	20
Design patents—		
Three years six months.....	10	10
Seven years.....	15	15
Fourteen years.....	30	30

The Lampert measure would also add the following fees: On every application for the reissue of a patent, \$30; on filing each disclaimer, \$10; on an appeal for the first time from the primary examiners to the examiners-in-chief, \$10, and on every appeal from the examiners-in-chief to the commissioner, \$20.

It will be seen that one slight increase is effected in the new measure in that \$20 instead of \$15 is to be paid with each application for a patent. This increase, with the additional fees, should amply provide for the increased salaries asked for and keep the patent office a money-making department for the government.

From these facts it can be seen that, although the commission attempting to work out an equitable method of fixing salaries of government employees might find a satisfactory solution to the problem, there are other matters of importance contained in the bill. The salaries and increased working force are, of course, of prime importance, for both these provisions will mean increased efficiency and that is the factor the manufacturer will be most affected by. The other items are worthy of consideration, however, and worthy of support.

### New British Society

A COMPARATIVELY recent body in England with a somewhat delicate but meritorious mission is the Society of Technical Engineers. According to the Journal issued by that body it has a twofold objective—the one connected with the interests of individuals and of the profession, and the other connected with the advancement of the British engineering industries. It will attempt to establish communications with individual employers and with organized employees in pursuit of both groups of its objects. In dealing with the manual workers, while the society will not associate itself with the labor movement nor seek to join the Trades Unions Congress, it will earnestly seek to find some means of co-operation with unions of manual workers in the industry in pursuit of the second group of its objects—those concerned with efforts to secure the advancement of the engineering industries of the empire.

It is the aim of the society, for the present, to make certain that technical engineers shall occupy and preserve a position intermediate between employers and workpeople, both within their firms and in relation to the organizations of employers and of workers. The society wishes to see the establishment of joint councils of employers and technical staff in suitable firms, which should in time come to discuss not only conditions but questions of technical engineering interest. The constitution of joint committees of technical staff and manual workers to consider means whereby the industry might be advanced would also be welcomed.

# The Economic Problem of Marketing

How can consumption be increased to fill manufacturing capacity and decrease price, without lowering wages, so that the product will be cheaper in relation to the purchasing power? This is the economic problem. It must be faced and can be solved only by decreased merchandising costs.

By Harry Tipper

**I**N the previous article upon this subject some indication was given of the position of the United States in its growth of manufacturing capacity. It was stated that the manufacturing capacity had increased beyond the present market requirements and that the problem of filling this manufacturing capacity was to a great extent a problem of economic marketing.

Most lines of industry find themselves facing a serious problem of over-production capacity and the discussions of all manufacturing associations are devoted largely to the attempt to find a solution to this problem. In the metal trades industry, for instance, some manufacturers have decided to enter other branches of that business in order to fill out their capacity for production.

This may provide a solution for some of the individual manufacturers, but it is only temporary, because every line has a larger production capacity than is necessary for present consumption and the problem is not improved by shifting individual organizations from one line to another.

In the endeavor to secure a sufficient proportion of the market to keep the individual factory running at individual capacity, the competition will become keener and more ruthless, so that some of the factories in every line of business will be busy at full rate while others will have a percentage of idle time due to their inability to secure enough of the market.

Unless the manufacturing capacity can be used fully and intelligently, the interest upon the idle capacity investment will be a direct burden upon the industry, adding to the costs. Prices have a tendency to fall and this tendency will be continued with temporary fluctuations for some time. Only by manufacturing at full capacity and with the very best equipment can the price yield the proper profit.

The economic problem, therefore, may be stated in this way: How can we increase the consumption so as to fill the present manufacturing capacity and decrease the price without proportionately decreasing the wages, so that the product will be cheaper in relation to the purchasing power?

The same problem was faced by Great Britain after the Napoleonic Wars, and by this country after the Civil

War. The problem was solved by the introduction of machinery and mechanical aids to manufacturing and transportation, so that the production capacity grew very rapidly. The price of production decreased very steadily and at the same time the individual wages increased almost as steadily. From the Civil War to about 1900, this progress continued.

In the face of declining prices the growth of industry will depend upon the ability of the manufacturer to produce and market his product at lower prices without being obliged to reduce his labor in proportion. People will consume more product if it costs less in proportion to their earnings.

The method adopted in the solution of the problem which we faced at the end of the Civil War cannot be relied upon to solve the problem today. The mechanical equipment of industry can be improved very considerably, but the improvement will be slower because the fabric is so much larger, so much more complete and has developed to a much higher stage of efficiency.

Undoubtedly great improvements will be made in manufacturing costs. The productivity of labor can be increased by large percentages.

The character and capacity of machinery can be improved very greatly in almost any individual factory. The improvement in mechanics will not be made at the same pace, however, because any single improvement will have less effect upon the total costs.

On the other hand, the commercial costs of business have been increasing for a number of years. The efficiency of marketing and of all the commercial elements of the transaction have been decreasing, so that many of the economies secured in production has been cancelled by the additional cost demand as the production was completed.

The tendency of commercial costs is to increase. If the present tendency continues, a considerable part of the economy secured in production in the future will be absorbed by the increasing cost of the commercial transactions.

It is necessary, therefore, that the business of distribution and marketing with all its commercial elements be examined and analyzed, so that its costs are

---

**M**ARKETING does not mean simply getting an order. It means getting the order at a cost justified by the character and extent of the order and under conditions which will make it possible to maintain the market with the least expenditure of time and effort.

A careful analysis of marketing is necessary to make it possible to obtain orders in this way. Practically no analysis of any importance has been made of marketing in the automotive field. Money has been spent on purely speculative possibilities. The manufacturer with a thousand cars to sell has not hesitated to try to sell those cars to four million people and to conduct his business as though such marketing expenditures were entirely justified.

---

reduced or the increase of costs at present operating is eliminated.

In the automotive field it costs far too much to market a vehicle or an accessory after the manufacturing is done.

The economic problem facing the automotive industry is the same that faces every industry in this country: How to keep the plant full, to lower costs without lowering wages in proportion, so that the purchasing power is increased in relation with the product.

The most important subject for analysis in the solution of this problem is on the commercial side of the business establishment, the costs which go into marketing, distribution and financing of marketing and distribution, the commercial overheads and similar functions.

Practically no analysis of an important character has been made of marketing in the automotive field.

Money has been spent on purely speculative possibilities without any knowledge of the limitations of the market or its reactions. The manufacturer with a thousand cars to sell has not hesitated to try to sell those cars to three or four million people and conduct his business as though the expenditure of money in marketing work on that basis were entirely justified.

The same manufacturer has distributed his cars, without regard to distribution costs, in any part of the country from which he could secure an order. Manufacturers of accessories and materials and parts have attempted to get distribution in every retailer's establishment, spending the same time and effort upon all retailers, although the buying capacity, the stability and the value of the retailers as customers vary very greatly, so that a considerable proportion of them do not buy sufficiently to pay for the efforts actually expended upon them.

The effect of turnover upon the capital invested in completed stock has not been sufficiently analyzed. Dealers' and jobbers' establishments have been stocked with material which has not been properly marketed, so that it would not move quickly enough to pay the interest upon the capital involved. Not only that, but the capital involved in distributing stocks properly arranged can be turned over at compound interest because of the opportunity to reinvest it frequently.

No analysis has been made of the effect upon costs produced by a change in the rapidity of the flow of prod-

ucts in distribution and marketing. Consequently, the cost of getting goods from the factory door through the manufacturer's commercial departments, the distributor and retailer to the final user, is unnecessarily high and has a tendency to increase constantly.

Unless better means of analysis are adopted this cost will have a tendency to further increase, because the intensity of competition will be increased and the efforts required to overcome the competition will add largely to the costs of distribution.

The most important problem faced by the automotive manufacturer to-day, therefore, is the problem of analyzing and reducing his marketing costs by the elimination of the observable and avoidable wastes, the application of known statistics properly judged and analyzed, keener understanding of the necessities of the distributor and retailer, and a far better knowledge of the problems of the user in both his buying and his service requirements.

Some consideration will be given in the following articles to the elements of visible and avoidable wastes and to the other factors entering into the marketing costs in the automotive field.

The problem must be faced. The growth of the business will depend upon the intelligence with which the problem is attacked and the character of the answer.

No sane man could justify the expenditures which have been made on the plea of sales and marketing in the past ten years. The profits may have justified such expenditures, but the necessities of the business did not justify them at any time. The observable wastes, which could be easily calculated by the analyst without much study, have run into thousands of millions of dollars every year in this field, and there are other inefficiencies that add measurably to this total. Even the economies so-called that have been established in the marketing departments since the business depression, have been established without any particular analysis, so that valuable and efficient means of maintaining a market have been eliminated or curtailed in common with the wasteful means, and valuable activities within the organization have been reduced in the same proportion as those of less definite efficiency.

Marketing does not mean simply getting the order. It means getting the order at a cost justified by the character and extent of the order and under conditions which will make it possible to maintain the market with the least expenditure of time and effort.

## An Unusual Export Market

**P**UNTA ARENAS is the most southern city in Latin America. Situated on the Straits of Magellan, in the Chilean territory of the same name, it has a population of from 35,000 to 40,000 persons and is the entry port to a great sheep and cattle growing territory that stretches far to the northward. This territory, the development of which has no more than commenced, already requires many automobiles for its necessary transportation services.

The needs of the territory and of Punta Arenas have been only partially met, according to a letter from Jorge Skarmeta S., one of the dealers of that city, who writes to *El Automóvil Americano*, the Spanish dealer publication of the Class Journal Co., as follows:

"I believe that Punta Arenas is the last place in which the universal crisis is making itself felt, but not on as large a scale as is indicated by the news from other sec-

tions. Any improvement in the price of wool would quickly dispel any disturbance that might make itself felt.

"The slight crisis through which the city is passing, as you will see, is of a momentary nature and will disappear entirely with any improvement relating to the products of this section. As this is quite an extensive territory, its products will require automotive power to move them. At the present time nearly all the business concerns, even those on a small scale, need rapid transportation.

"For that reason you can see that this section deserves quite a little attention on the part of those who contribute to our automotive development. Not one-half as much has been done along these lines as would be possible in replacing unnecessary vehicles drawn by animals."

## Reduction of Unsprung Weight

**Q**UITE the most interesting design of car at the recent Berlin show evidently was the Rumpler. The mechanical features of this car may be considered distinct from its extreme body lines, which are unlikely to appeal to American eyes. As regards the chassis, most interest attaches to the rear axle construction, which tends to materially reduce the unsprung weight. The first move in the direction of reducing the unsprung weight of the driving axle was made by De Dion as long as 20 years ago. On the car referred to the differential was suspended from the frame and the rear axle was made tubular and curved to the rear so as to clear the differential housing. Two universal joints were incorporated in each axle shaft, so that the chassis frame could move freely in a vertical direction relative to the axle without interfering with the drive.

This design improved the riding qualities, reduced tire wear and relieved strains on the chassis parts; but these advantages are gained at the expense of

the use of four universal joints, each of which had to have about four times the torque capacity of a joint in the propeller shaft. Notwithstanding this drawback, De Dion used this form of rear axle for many years with entire satisfaction.

The tendency to reduce the unsprung weight is persistent. Numerous American manufacturers have tried out the transmission axle, in which the gearset is mounted at the center of the rear axle, but one after another they have given it up again. The reason is that the additional unsprung weight represented by the transmission in such cars is a detriment in every respect; it is hard on the car and hard on the occupants. Manufacturers using this construction sometimes made determined efforts to lighten their rear axles in other ways, as by the use of aluminum centers and alloy steel tubing and shafting, and in one or two cases the claim was made that the transmission axle weighed no more than plain axles on similar cars of less refined design. Yet the fact remained that if the gearset were carried on the chassis frame the unsprung weight would be reduced by just that amount.

In an effort to further cut down the unsprung weight several engineers in recent years have designed cars without a rear supporting axle, the weight of the chassis being transmitted to axle stubs by a combination of cross springs. Tests have shown that cars of this type are exceptionally soft riding. Similar riding qualities should be obtained by the Rumpler construction, because both the arrangement of the axle and the use of the cantilever type of spring tend to cut down the unsprung weight, which should not be much more than that in a car without supporting axle. Over the De Dion type the Rumpler axle has the advantage that it dispenses with the need for universal joints. An axle of this type could be used on a car having the engine located under a bonnet in front, and in such combination it would probably stand a better chance of success—in countries outside Germany, at least—than in combination with the rear-mounted engine and the ultra type of body.

## New English Buses

**L**ITTLE buying developed at the Olympia truck show in England. It is interesting to note, however, that what buying did take place was largely in the motor bus field. There were numerous inquiries for new motor coaches and omnibuses, and the indications are that firms which have made a reputation in this field of construction will profit considerably from the show.

While the general business depression appears to be seriously hindering any upward movement in British truck sales in general, the bus transportation interests are not seriously hampered by general economic conditions. Bus transportation has already taken a definite place in the British transportation system, and consequently bus companies are appearing as welcome buyers at a time of general depression.

A similar development of the bus movement in this country might furnish similar help to our truck industry.

## A Message for Business

**T**WO historic events will take place in Washington next week. The stage has been carefully set for each, but with vastly different trappings. One will make history for a world in need and the other will be a dramatic reminder of history already written, but each bears a close relation to the other.

Business and industry, intent upon their immediate and individual problems, appear to have given scant thought to the significance of these events. World peace for the future and the great war which has gone by seem in some way remote from the manufacture, sale and transport of commodities, but those who seek the connection need not dig deep to find it.

Business has been bound up inextricably in every event which has happened since an Austrian archduke was slain at Sarajevo eight years ago and the world was set on fire. Business boomed and profits soared to unexampled heights while the drum-fire of cannon was heard from one end of Europe to the other. It was an inevitable concomitant of war. It was equally inevitable that the greater portion of those profits should vanish in the reconstruction of a world left rocking on its foundations when peace was signed and slaughter ceased.

It may seem a far cry from a survey of business to-day to a retrospective glance at the battlefields of France; from the study of a balance sheet to an international conference on the limitation of armaments. Each cause has its effect, however, and little happens in the world in which business does not play a part.

The nation has been asked to stand at salute for two minutes at noon of Armistice Day while an unknown soldier of the Republic is being buried in the hallowed soil of Arlington, where heroes sleep. The war lords who gather there and the elder statesmen of the nations they serve will meet in solemn conclave the next day to determine whether the crushing burden of armament cannot be lightened.

Soldiers and sailors with reversed arms, led by the commander-in-chief of the army and navy, will march behind the caisson bearing the flag-draped casket, to the measured cadence of funeral dirges. Great soldiers will pin upon the coffin tokens of valor taken from their own breasts. The simple soldier who gave his life that democratic ideals might not perish will win in death the Congressional Medal and the Victoria Cross, heritages of heroism. Gold star mothers will mingle their tears over the bier of the boy who might have been their son. No honor will be great enough for the unknown lad who fell in France, for he will be symbolic of all those who made the supreme sacrifice.

This solemn ceremony should do more than evoke a thrill of patriotic pride and a pang of sorrow in the hearts of Americans. They would do well to bow their heads and offer up a silent prayer of thanksgiving to the God they serve that they are citizens of the United States. Americans are fortunate, indeed.

They are not crushed under a load of taxation which is sapping their financial strength. Their nation is not standing on the verge of bankruptcy, battling bravely to keep from going over the brink. Their currency is at a premium the world around. Their mills and factories and municipalities are solving the problem of unemployment. They are not confronted daily by the spectre of another war. Opportunities for success are theirs to-day, as they were yesterday and will be to-morrow.

America suffered scarcely at all in the welter of war, and, in comparison with other nations, it knows nothing of the agonies of peace. It knows nothing of the stupendous problems of reconstruction and readjustment. The path to prosperity lies straight before it with only a few stones to be cleared away.

Have business men no interest in the symbolic burial of the unknown or in the arms conference which will follow it? Does it mean nothing to them that their nation, which need fear no foe, is leading the way in striving to lighten the burden of the world by cutting down the cost of armies and navies?

Do they want no part in turning the world toward a peace which shall endure and a prosperity which shall be great enough for all to share?

There is a message for business in the pageantry and pomp which are only a week away.

# Car Shipments Show Slight Decline

## Equal in Volume to Last October

### Truck Business for Third Quarter Proves Better Than for Second

NEW YORK, Nov. 1—Shipments of automobiles for October were only 11 per cent less than the preceding month and for the first time since the process of liquidation began they were virtually the same as shipments for the same month of 1920. There is every reason to believe that from now on comparison of shipments and production will show a gain over the same month in the previous year.

The October showing is better than had been expected. Manufacturers believed at the beginning of the month that there might be a considerable decline in sales, but they have been pleasantly disappointed. October last year was 26 per cent less than September.

Truck sales are showing a slow but steady growth, and business for the third quarter was better than for the second, which ran approximately 100 per cent ahead of the first. Several of the larger companies have a substantial number of orders on their books.

Export business is slowly looking up. Canada and Mexico are among the best foreign fields at this time for American automobile manufacturers. Conditions in South America and the Far East are more satisfactory, and sales are gaining slowly in almost every quarter of the world except Continental Europe.

Factory operations this month will be carried on with caution. A few factories propose to increase their schedules to meet business on hand or in prospect. This is true particularly of those manufacturing cars in the higher price classes. On the whole, however, production schedules will be made flexible and the output will be governed entirely by actual sales.

While sales as a whole show little tendency to slacken, notwithstanding the approach of winter, manufacturers generally look for a tapering off in business between now and Jan. 1; but they have expected about the same thing every month since June. For that reason it may be pos-

## M. A. M. A. SEPTEMBER BUSINESS SHOWS GAIN

NEW YORK, Nov. 1—The volume of business done by members of the Motor and Accessory Manufacturers Association for September showed a slight gain over August. This marked the seventh consecutive month in which total sales showed slight variation. It is significant, however, that June was the only month to show a decrease as compared with the preceding month. Another striking fact shown in the report is that there was a change of only 00.22 per cent in the volume of past due accounts in September. For the first time since March there was a slight increase in the total volume of notes outstanding. The figures for each month this year follow:

Month	Total Purchases	Per Cent Change	Total Past Due	Per Cent Change	Total Notes Outstanding	Per Cent Change
January .....	\$6,264,587		\$8,099,727		\$4,359,871	
February .....	10,408,962	66.15 Inc.	6,717,165	17.07 Dec.	6,063,118	39.08 Inc.
March .....	20,120,386	93.30 Inc.	5,603,992	16.57 Dec.	5,069,877	16.38 Dec.
April .....	26,746,580	32.93 Inc.	5,352,271	4.49 Dec.	5,371,086	5.94 Inc.
May .....	26,781,350	.13 Inc.	4,505,176	15.64 Dec.	4,460,355	16.77 Dec.
June .....	22,703,414	15.19 Dec.	4,720,973	4.79 Inc.	4,012,670	10.37 Dec.
July .....	23,096,214	1.68 Inc.	5,242,046	10.79 Inc.	3,690,154	7.90 Dec.
August .....	23,397,640	1.31 Inc.	4,348,790	17.06 Dec.	3,494,510	5.30 Dec.
September ....	23,141,891	1.09 Inc.	4,358,545	00.22 Inc.	3,677,500	5.24 Inc.

sible that November business will exceed their expectations.

The fundamental strength of the industry and the deep interest of Americans in motor vehicles is evidenced by the fact that sales for the last seven months have varied only slightly from month to month and have been in volume sufficient to keep the industry as a whole, including many of the smaller plants which have done practically nothing, running at more than 50 per cent of capacity.

## Milwaukee Manufacturers Report October Increase

MILWAUKEE, Oct. 31 — Activity among manufacturers of passenger cars, engines, parts and equipment in Milwaukee during October showed on the broad average a slight gain over September. A few shops fell below the previous month's mark, but the majority were able to hold their own or to establish a somewhat better position. This is encouraging in view of the fact that September was not quite up to the August volume.

Makers of motor trucks and motor truck parts and equipment are in a more cheerful attitude than since last spring, due to an upturn in sales. Cold weather is expected to accentuate this advance in some directions and cause a reaction in others, so that opinion seems to be in favor of no marked activity in truck merchandising until spring. Export business in motorcycles is running better than expectations.

The export market is the principal one for this class of automotive merchandise, as many domestic prospects are able to buy a four-wheeled motor vehicles as cheaply as a cycle, and economy of operation is the biggest inducement for the purchase of cycles.

## Harper Will Direct Sales for Studebaker

SOUTH BEND, IND., Oct. 31—Harry B. Harper, former president of the National Automobile Dealers Association and until recently the largest distributor of Willys-Overland cars, has been appointed sales manager of the Studebaker corporation. He will assume his new duties Nov. 7.

Harper's reputation as an automotive merchandiser is country-wide and has been gained by nearly 20 years of selling experience. He retired as advertising manager of Bowser & Co., Fort Wayne, in 1905 to become advertising manager for the Ford Motor Co. In 1907 he was made assistant to Norval Hawkins and in 1909 became Ford's first foreign manager. His work with the Ford company attracted the attention of John N. Willys and in 1911 Harper organized the foreign department of the Willys-Overland company. A year later he was made assistant to the sales manager and in 1915, 1916 and 1917 he was general sales manager for the Willys-Overland company.

## Harper Long Distributor

Harper became Philadelphia distributor of Willys-Overland cars in 1918 and six months later he raised that city to first place as an Overland distributing center. He was sole owner of this business until the Overland company announced a new policy and established a direct factory branch in Philadelphia. Throughout his activities as head of an automobile sales organization, Harper has taken a deep interest in the affairs of his dealers. He has studied their problems from every angle and tried to give practical assistance. Few men in the country have wider dealer acquaintance than Harper.

# C. O. Miniger to Join Durant Motors

## Severs Connection with Willys by Jan. 1

### Electric Auto-Lite President Will Become Director of Durant Subsidiaries

NEW YORK, Nov. 2—Clement O. Miniger, vice-president of the Willys Corp., as well as president and general manager of the Electric Auto-Lite Corp., will sever his connection with the Willys organization some time between now and Jan. 1 to become associated with W. C. Durant in the management of Durant Motors, Inc. No formal announcement of Miniger's plans has been made, but he will be a director of several Durant subsidiaries, including the Durant Motors Co. of Canada, Ltd. It has not been determined whether his headquarters will be in New York or Toledo.

Miniger ranks next to Walter P. Chrysler and J. R. Harbeck in the Willys Corp. He is credited with much of the success of the Electric Auto-Lite Corp., which has had a comparatively satisfactory business all through the period of depression, and is now in a highly satisfactory position.

The Electric Auto-Lite Corp. was organized by Miniger in 1911 and he became secretary and treasurer of the company. When John N. Willys associated himself with the corporation three years later Miniger was elected president and general manager. He has continued to occupy that position ever since. He also is president of the Fostoria Machine & Tool Co. of Fostoria, Ohio, vice-president of the Burt Foundry Co. of Toledo and director of the National Bank of Commerce and the Morris Plan Bank, both of Toledo.

Born on a farm at North East, Pa., on Nov. 11, 1874, Miniger was taken to Ohio by his parents at an early age and was educated at the Fostoria high school. He later took a course in pharmacy in Chicago after which he went to Toledo and entered the employ of a wholesale drug house as traveling salesman. He held this position for 10 years. His first business venture was the operation of a coal mine at Cambridge, Ohio, with offices in Toledo. He remained in that field for three years and then manufactured paper boxes for a like period.

There are reports, as yet unconfirmed, that another prominent figure in the automotive industry who soon will join

Durant, will be Hugh Chalmers, who gained wide fame with the National Cash Register Co. before he entered the automotive field. His last active work in connection with automobiles was with the Chalmers Motor Car Co., which now has been merged with the Maxwell Motors Corp. He was president of the Chalmers company until the reorganization in 1918 when control was acquired by J. S. Bache & Co., bankers.

## To Reorganize Signal Under Michigan Laws

DETROIT, Nov. 1—The Signal Motor Truck Co., a Maine corporation for which a receiver was appointed in Portland on Aug. 17 by Federal Judge Hale, will be reorganized this week as a Michigan corporation. It is learned that the property of the company was taken over Oct. 26 by a former officer as an individual pending the reorganization. The new company will retain the same name and there will be no change in its products.

The petition for a receiver was filed by Milton B. Hoagland, vice-president and general manager of the company, in accordance with a vote of the stockholders. The Maine company has outstanding \$548,000 in common and preferred stock in addition to a funded debt of \$190,000 in bonds and \$220,000 in notes. J. G. Heaslet was president of the old company and H. H. Emmons was secretary.

## Cunliffe, Branch Head, Leaves to Join Collins

CHICAGO, Nov. 1—C. R. Cunliffe, for more than ten years associated with the Cadillac organization, has resigned from the general managership of the Chicago branch of the Cadillac Motor Car Co. to become associated in an executive capacity with R. H. Collins, former Cadillac president and now president and general manager of the Peerless Motor Car Co. of Cleveland.

Cunliffe came to this city Aug. 1, 1919, for the purpose of opening the local branch, the understanding being that after its establishment he would take up other work. During his administration the floor space used by the branch has been more than tripled, necessitating the erection of a new service building. Previous to coming to Chicago, Cunliffe served as manager for the Cadillac distributor in Philadelphia.

His successor here is L. B. Sutherland, who has been associated with him in various capacities. Sutherland, who is a resident of Chicago, has been sales manager of the Chicago branch for the last two years.

## New Gray Product to Be in \$500 Class

### Output Will Start Early in Year—12 Points for Assembling Cars

DETROIT, Oct. 31—F. L. Klingensmith, president of the Gray Motor Corp. and former vice-president and treasurer of the Ford Motor Co., has announced that the new Gray car will be priced at approximately \$500 in the open models and will be in production following the first of the year. Associated with Klingensmith in Gray Motors is Frank F. Beall, former Packard vice-president.

The Gray car will be shipped in a knockdown condition to 12 assembly points in the country, the engine and parts to be made in the Gray plant here which is to be enlarged. The Gray car has been in development for more than a year, its introduction being deferred until the market was considered satisfactory.

The car follows the usual lines, having a four cylinder engine and will be made so as to be readily assembled. It will have a 100 in. wheelbase and be made of alloy steel. The company is capitalized at \$4,000,000, which is said to be the nucleus of a planned \$50,000,000 corporation.

In a statement of his plans, Klingensmith declares his knowledge of low-priced motor cars gives assurance that he will be able to build a motor car which will compete successfully with the world. He adds that this was what he had in mind when he retired from the Ford organization. His plan of operation calls for the purchase of all parts except the engine.

It is stated that \$1,500,000 already has been put into the company and that an additional \$2,500,000 in stock will be underwritten. The first \$500,000 will be 10 per cent preferred to sell at \$10 a share.

The directors of the company are Klingensmith, Frank F. Beale, Paul R. Gray, David A. Brown, J. H. Poole, George H. Kirchner, H. B. Hoyt, O. J. Mulford, Benjamin S. Hanchett and Luman W. Goodenough.

## MILLER RETIRES AS JOBBER

NEW YORK, Oct. 31—Charles E. Miller, who has conducted for years one of the largest automobile supply houses in the United States, has decided to retire from the general automobile jobbing business. He will establish himself as a manufacturers' agent after selling his present business as a going concern.

## Trucks Led Federal Plan to Meet Strike

### Arrangements Evolved by Government Will Probably Stand for Future Emergencies

WASHINGTON, Oct. 31—Plans of the Federal Emergency Organization for the movement of necessities in case of a railway strike, as made public by Secretary of Commerce Hoover, show that the motor truck was the keystone of the Government's transportation plan. Everything was in readiness for the strike, which was called off. The Motor Transport Division was created with Windsor T. White, of the White Truck Co., as chairman, and Gordon Lee, chief of the automotive section, Department of Commerce, as his assistant.

#### Headquarters in Washington

The plan of operation drafted for the emergency will undoubtedly hold good in the event of a similar condition arising in the future. The organization was to have had headquarters in this city with its primary object the handling of interstate and inter-regional problems, and all other activities were to be left to the local initiative of Governors' organizations.

The program called for the determination of the primary, secondary and tertiary stocks of food, fuel and feed throughout the country. Primary stocks were those available within State radius; secondary, those within interstate water and motor radius; and tertiary, those within interstate rail and water radius.

It was also planned to determine the areas dependent upon interstate movement for supplemental supplies. Furthermore, it was believed advisable to ascertain the character of movement, whether by water, rail or truck, required or available.

#### Local Surveys Also

The Federal authorities, after a series of conferences, arrived at the conclusion that trucks should head the list of transportation units. In addition to the Federal survey they planned to have each locality make its own survey of commodities and the transportation problem. One of the significant features of the plan shows that the utmost reliance was placed upon the efficiency of truck operation. The official report of the plan as distributed to the State organizations, contains statements that two alternatives would be apparent in the service: first, that the railways cease operation and that reliance be placed solely upon trucks and water; and second, that limited operation of railways would be maintained.

The Department of Commerce plans to supply graphic maps to State committees showing primary reserves of each commodity available without movement. They intend also to make known the secondary reserves which could be obtained by motor and water movement. The plan called for the establishment

of priorities on commodities. It was the idea of the Department to make reports to individual organizations as to truck transportation available and truck mobilization for long and local hauls.

Assuming that railroad operations ceased entirely, it was pointed out that all towns and cities outside the "dense area" could supply themselves by motor or water for at least sixty days without any consequential interstate movement. The "dense area" comprised New England, New York, New Jersey, Delaware, Maryland, Pennsylvania, Ohio, Indiana and Illinois. It was suggested that steps be taken by the local authorities in anticipation of any difficulties to supply gasoline.

The Department of Commerce declares that two primary changes in the situation from pre-war conditions are to be noted: first, by war experience the country understands the whole process of civilian and industrial organization to meet emergencies; and second, the motor truck has given every town an extended radius of food supplies by some 50 miles and thereby protects such vital matters as milk and perishables against the first shock.

The automobile industry has been much concerned over the mobilization points which the Government would select in the event of a strike. The Department of Commerce divided the country into regions under regional representatives. The first region covering the New England States centered at Boston; the States of New York, New Jersey, Delaware, centered at New York City.

(Continued on page 897)

## Darrow and Dinsmore Join Goodyear Tire

AKRON, Nov. 1—Burgess Darrow has been appointed development manager and R. P. Dinsmore chief compounder for the Goodyear Tire & Rubber Co. following the resignations of W. S. Wolf and W. P. Keith.

Wolf and Keith have joined the staff of Frank A. Seiberling, formerly Goodyear president and now owner of the Lehigh Rubber Co. at New Castle, Pa., and organizer of a plan to amalgamate a number of smaller rubber factories into one large corporation.

The resignations are in line with others which have been previously announced and others expected as Seiberling completes his new organization.

The resignation of K. B. Kilborn as experimental engineer to be succeeded by V. V. Messer has also been announced by Goodyear.

Darrow and Dinsmore are graduates of the Massachusetts Institute of Technology in chemical engineering. Darrow came to Goodyear ten years ago in development work in the California Goodyear Co.

Dinsmore has been with Goodyear eight years and was in charge of compounding work several years ago when he assumed the same duties at the Canadian Goodyear plant.

## Malleable Castings Discussed by S.A.E.

### Better Understanding Regarding Their Use Urged at Cleveland Sectional Meeting

CLEVELAND, Nov. 1—More than 70 members of the Cleveland section of the S. A. E. listened to an address by H. A. Schwartz, manager of the research department of the National Malleable Castings Co. on malleable castings in the automotive industry. Most of the talk was made in explanation of lantern slides.

There is too much misunderstanding regarding the use of malleable castings in the motor car, Schwartz showed in reciting cases of certain cars which have 31 malleable castings but which the sales organizations often declare have none at all.

To-day the malleable casting industry is at 35 per cent capacity. There are 176 manufacturers of malleable castings, all of them being located east of the Mississippi River. Two electric furnaces are used in the manufacture of such castings, but no difference in the merchandising of these products is being made. One difficulty in the manufacture of malleable castings little appreciated in the motor industry, it was stated, is that nine days are needed in the proper annealing. Too frequently purchasing agents are delinquent in placing orders and become impatient at the delay in receiving shipments, which is due largely to the time needed for correct annealing.

The council of the S. A. E. met here in order to be present at the Cleveland sectional meeting. President David Beecroft addressed the latter on the necessity of sections using part of their program in better selling the standards that have been adopted by the society. One manufacturer of bolts and nuts is saving \$500 on these products daily due to S. A. E. standardization. As yet there is not so wide an appreciation of the dollar and cent valuation of standardization as there should be, he said, and urged that the S. A. E. members sell the work to their own executives.

## Auto Body Co. Awarded Contract by Durant

DETROIT, Oct. 29—Auto Body Co. of Lansing has been awarded the contract for all open bodies for Durant Motors of Michigan, whose plant at Lansing is ready to launch production in November.

The body company after making the necessary equipment arrangements will start at once upon the Durant work, deliveries going forward at once and continuing through 1922. The styles of the bodies have been laid down by Durant engineers and will be along conventional lines. A large number of men will be added to the force now employed to meet the new contract demands.

## Sees Motorization of Interurban Cars

### Truck Maker Receives Inquiries As to Types and Costs of Engines

CLEVELAND, Nov. 1—The truck business in Cleveland is picking up. While the passenger car business has held up well in the Cleveland territory during the first three weeks of October, there has been a slight decline as compared with the corresponding period last month. This decline in October in passenger car business is said not to be so great on the average as it has been in other years.

Peerless Motor Car Co., for instance, reports that October business is on a par with September. The Stearns Co. reports that its passenger car business increased in October. There may be other exceptions in this city, but it may be fairly stated that there has been a slight falling off in volume.

#### Public Utilities Interested

Both the passenger and motor truck business was much better during the first three weeks of October this year than it was in the same month in 1920, according to reports.

At the general offices of the White Co., the prediction was made that in the immediate future there is to be a great development of business with certain public utilities that are now operating their cars at a loss with electricity.

The motorization of the interurban systems of the country at no great future date was predicted and, in substantiation of the prediction, White officials said that many inquiries are being received from interurban companies about types of engines that could be used and the cost.

The interurban roads in Ohio have been down-at-the-heels for years. Most of the companies have paid no dividends and they have been steadily losing business to motor buses in late years. Stocks in the companies are far below par and a great many shares have no market.

#### Operation Costs Less

It costs about \$3 a mile to operate an interurban car with electricity, while it can be done for less than a dollar with a gasoline engine, according to statements made at the White company. The State Public Utilities Commission has found the interurbans to be a millstone under existing conditions that they cannot shake. Motor vehicles are hauling much of the freight that formerly was delivered to the electric cars. A large element of the traveling public that used to ride in interurban cars are now using either their own automobiles or the public motor buses.

The Ohio Public Utilities Commission has had its attention called to the advisability of changing from electricity to the gas engine. Several interurban lines have shown enough interest to write the

White company about the subject. The utilities commission would have to authorize a bond issue, as the interurban lines now have hardly sufficient money to operate their plants.

The motor truck is the center of attention temporarily, at least, on account of the publicity that was given the threatened railroad strike. In every community the motor truck resources were offered to the mayor. The truck as an agent for short hauls was brought forward in a manner by the proposed strike of railroad employees that created a good will of inestimable value.

### Hares Motors Completes Plan to Handle Thomart

NEW YORK, Oct. 31—Hares Motors, Inc., has practically completed negotiations with the Thomart Motor Co. of Kent, Ohio, under which it will take over sales of the Thomart truck.

President Thompson of the Thomart company, in announcing that a contract had been agreed upon, stated that the plant at Kent would be placed on a highly efficient basis to meet the increased business which is expected. The company manufactures a light speed truck.

The fact that Hares Motors is taking on this new line will have no bearing whatever on the continuance of its selling arrangement with the Kelly-Springfield Truck Co.

### French Automobile Salon Draws 463,285 Visitors

PARIS, Oct. 22 (*By Mail*)—Nearly half a million persons paid for admission to the French Automobile Salon during the twelve days the Grand Palais was open to the public. The exact official figure for paid admissions is 463,285, giving gate receipts totaling 1,555,849 francs, or about \$112,000 at present exchange. The biggest crowds were received on the last day of the show, when 57,499 persons paid to pass through the turnstiles.

At the last show held in 1919, 438,552 persons entered the Grand Palais.

#### REORGANIZING STANWOOD

NEW YORK, Oct. 31—Plans for the reorganization of the Stanwood Rubber Co. provide for the issuance of \$300,000 in first mortgage bonds; \$500,000 in first preferred 8 per cent stock; \$151,000 in second preferred; \$175,000 in debentures and \$50,000 shares of no par value common. The creditors will receive 50 per cent of their claims in debentures and 50 per cent in new common based on a value of \$2 a share.

#### NEW ARMLEDER TRUCK

CINCINNATI, Oct. 31—The O. Armleder Co. is bringing out a new Model 30 with a capacity of 1½ tons. This will fit in the line between the present Model 20 and the Model HW. The engine is a Buda, 3¼ x 5½ in., wheelbase 147 in., and final drive by Timken worm type axle.

## Maibohm Receiver to Continue Plant

### Petition in Bankruptcy Filed to Save Company—Creditors Have Refinancing Plan

TOLEDO, Nov. 1—Efforts to save the Maibohm Motors Co., Sandusky, through a reorganization were the basis for a petition in bankruptcy filed in Federal Court here last Friday. The assets of the company are listed at \$759,124.38 and debts at \$681,640.11.

Judge John M. Killits appointed W. J. Corr, secretary of the company, as receiver with power to continue the business. The property of the company was ordered sold.

A creditors' committee filed a similar petition with a plan for re-financing attached. Edward Kirby of the Commerce Guardian Trust & Savings Bank, Toledo, is chairman of the committee. The plan is to pay outstanding indebtedness with the proceeds of an issue of preferred stock.

#### Plant Fire Responsible

Difficulties of the company are said to be due to efforts to recover from a disastrous fire which swept away the plant at Racine, Wis., before the company moved to Sandusky.

A statement issued by the Maibohm company says that "unless unforeseen obstacles arise the receivership will terminate Nov. 14 and the reorganized company will take charge." It is stated that there will be no interruption of manufacturing operations.

The committee which has worked out the reorganization plans is headed by R. E. Hayslett, treasurer of the Hydraulic Steel Co. of Cleveland, N. T. Brotherton, president of the Brotherton-Knoble Co. of Detroit, and E. G. Kirby, vice-president of the Commerce Guardian Trust & Savings Bank of Toledo. All three are directors of the company.

#### Succeeded Former Company

The Maibohm Motors Co. was incorporated in Maine in 1917 as the successor to a company of the same name incorporated in Delaware a year earlier to take over the business and assets of the Maibohm Wagon Co. and Maibohm Rubber Co.

The authorized capital stock is \$2,500,000 of which \$1,780,000 is outstanding. There is no funded debt. Gross sales for the year 1920 were \$1,897,658. The surplus for the year after payment of taxes, etc., out of the profits, \$51,503, was \$2,213.

H. C. Maibohm has been president of the company since its organization and recently has acted as general manager.

The plant of the company at Racine was burned Dec. 31, 1918, and it was decided to accept an offer from the city of Sandusky of 15 acres of land with a cash bonus of approximately \$100,000. The new plant in that city has 75,000 sq. ft. of floor space.

## Durant Car Sales Total \$31,000,000

Contracts Signed up to Oct. 22  
Call for 30,842 Deliveries  
by July 31, 1922

NEW YORK, Nov. 1—Durant Motors, Inc., has made public a remarkable affidavit signed by M. B. Leahy, general sales manager of the Durant Motor Co. of New York which controls the manufacture and sale of Durant cars for the New England and Atlantic Coast territory.

In his affidavit Leahy says that although the first Durant car was not placed on exhibition until Aug. 4 last, he had received at the close of business Oct. 22 a total of 24,817 shipping orders, based on signed contracts with deposits, for the four cylinder car, and 6025 contracts for the six cylinder car, or a total of 30,842. The contracts specified deliveries dating from Nov. 1 up to July 31, 1922.

Total Expense, \$15,416

Leahy declares that this business, approximating \$31,000,000, was obtained without the assistance of traveling men and that the total expense, including both sales and service departments, was \$15,416 or an equivalent sales cost of one-twentieth of one per cent.

The assertion is made by Leahy that in his judgment the territory covered by the Durant Motor Co. of New York will produce a volume of business requiring the production of 140,000 automobiles in the next nine months.

Durant Motors, Inc., has issued a statement confirming the report that a contract has been closed with the Continental Motors Corp. for all motors for the Durant four cylinder car which will be made at Long Island City, Lansing, Oakland and Toronto. The statement says:

### Continental Makes Ready

"That contract just closed provides for a minimum of 100,000 motors and involves, it is understood, between \$12,000,000 and \$15,000,000. The motors are to be built according to the specifications of Durant engineers.

"This is believed to be the largest single transaction in automobile parts negotiated.

"An interesting side-light in connection with this contract, which indicates the degree of confidence existing among big business men, is brought out in an interview given by President Judson of Continental Motors in which he states that upon Durant's assurance last April, when an order for a sample motor was placed, that a mutually satisfactory contract would eventually be signed, and upon Durant's verbal assurance only. Continental Motors invested in tools and special equipment necessary to expedite production upwards of \$700,000."

### LIMITS TIRE RECEIVERS

CLEVELAND, Oct. 31—Federal Judge Westenhaver has issued an order permitting operation of the Republic Tire & Rubber Co. of Youngstown and Canton under the receivership until further orders of the court. He declined to order continuance of the receivership for a

## MILEAGE GUARANTEE REPORT COMPLETED

NEW YORK, Nov. 1—The special committee of the tire manufacturers' division of the Rubber Association of America, which has been investigating all phases of the tire mileage guarantee, has presented its report to the division for adoption or rejection by the individual manufacturers.

While the report will not be made public until it is known definitely whether the general sentiment favors its acceptance, it is understood to recommend strongly the abolition of mileage guarantees. This is done on the theory that all reputable tires are good for more than the number of miles guaranteed and for that reason nothing is to be gained by continuing the practice. It is understood there is little doubt that the recommendations of the committee will be accepted.

year. The receivers are directed not to make contracts for fabric and other materials more than six months ahead.

## Goodrich Tire Completes Preferred Dividend Year

AKRON, Nov. 1—The B. F. Goodrich Co. has successfully completed the year of preferred dividend payments. The directors' meeting at Akron, Oct. 26, provided for the preferred dividend of \$1.75 a share payable on Jan. 2 to stockholders of record Dec. 22.

Although the statement to the directors by the officers of the company was not given out it was characterized by members of the board as exceedingly satisfactory.

The company has recently increased production to approximately 9000 tires a day after having sold two tires for each one manufactured during the past year.

The entire organization has been combed and placed in readiness for the expected increase in business early in the new year. Approximately 500 men were put to work immediately after inventory taking and this force will probably be gradually increased as the new year approaches and advances.

The company recently announced that the floating indebtedness of more than \$30,000,000 has been reduced by \$23,000,000 during the past year and that sufficient cash is on hand to liquidate the balance.

### COMMERCE SETS PRICES

DETROIT, Nov. 1—The Commerce Motor Car Co. announces prices on the new Commerce truck as follows: 1½-ton (pneumatic equipped) \$1,450; 1½-ton, \$1,695; 2-ton, \$1,995; 2½-ton, \$2,150. Pneumatic equipped on the three latter are \$1,800, \$2,150 and \$2,495.

## Government May Buy Highway Motor Stock

Subscriptions, Under Senate Bill,  
Would Constitute Loan to  
Corporations

WASHINGTON, Nov. 1—Senator Sheppard has introduced a bill to encourage highway motor transportation in this country by authorizing the Government to subscribe for stock in organizations created for the purpose and for the establishment of a national highway motor transportation bureau.

The bill provides that the sum of \$100,000 be appropriated to enable the proposed motor transportation board to secure such expert assistance as it may deem advisable in carrying out the purposes of the proposed act.

Another appropriation of \$7,200,000 would be authorized for the purchase of stock in corporations and would be issued by the Secretary of the Treasury to the corporation specified by the trade.

### Provisions of Measure

The measure, which is known as S. 2631, further provides that it shall be shown to the satisfaction of the board (a) "that a corporation is in process of organization within a state, territory, or the District of Columbia, by reputable and reliable persons for the purpose of operating a highway motor transportation route at least fifty miles in length; (b) that the plans, resources, capital stock, rates, personnel, material, and probable business of such corporations are, or will be, of such nature or amount as to offer reasonable hope of success; (c) that the laws of the state, territory, or District in which the route is to be operated provide proper protection for the permanent operation of the corporation and proper construction and maintenance of the highway or highways to be utilized by the corporation. Under such conditions it is provided that the board for and in the name of the Government of the United States shall subscribe the last fourth of the capital stock of the corporation remaining unsubscribed."

### Stockholders Must Apply

The proviso is inserted that application for such subscription must first be made in writing by the stockholders of the corporation over verified signatures. The rate of interest is fixed at 10 per cent. The amount paid by the Government will constitute a loan to the corporation, repayable with interest at the rate of 5 per cent per annum in ten annual installments, the first installment to be due five years after the date of subscription.

The issuance of stock is limited to six corporations within one State, territory or District of Columbia. Under the Sheppard bill, corporations would be obliged to make annual reports covering transactions and progress during the preceding year. There is a provision in the bill which prohibits the purchase of other stock unless subsequently authorized or directed by Congress. This bill has been referred to the committee on interstate commerce.

## Trucks Have Forced Lower Rail Rates

### Competition Impelled Executives to Ask for Revised Tariffs on Commodities

WASHINGTON, Nov. 1.—Competition by automobile trucks has forced railroads to lower freight rates in cases where every other argument has failed. A study of the recent decisions of the Interstate Commerce Commission by a representative of AUTOMOTIVE INDUSTRIES showed that the cost of hauling by truck has decreased, while the rail carriers are finding it difficult to bring about economies essential to rate reductions.

The fact that several short line railroads have suspended operations owing to truck competition is a disturbing factor in the present agitation for cuts in freight rates. There has been some talk of regulation of motor trucks by the Federal Government but there are few who anticipate such action. It is believed that Federal regulation would find little favor in Congress at this time. Some traffic experts insist that laws regulating rail carriers would not be applicable to trucks.

#### Numerous Instances Shown

As to the effects of truck competition, the records show that there have been numerous instances where rates on commodities have been reduced on the request of rail carriers. Lincoln Green, vice-president of the Southern Railroad, very frankly admits that competition of trucks forces the lines to reduce their freight rates. He says:

"Our purpose in making these reductions in short-haul rates on cotton was primarily to meet truck and wagon competition not merely within the short radius of the consuming center, but for longer distances to which truck service has been extended, not merely taking cotton away from us at actual railway shipping points, but engaging in the transportation of other commodities in both directions.

"The matter has been under consideration for more than twelve months and our action is now taken in the belief that it is in the interest of the conservation of our revenues. Whether the proposed rates will actually enable us to meet the competition and continue to control a share of the traffic is a matter of experiment."

#### Truck Operation Decreasing

Just how it is possible for trucks to quote lower rates for the transportation of commodities has been illustrated by R. A. Brand, vice-president of the Atlantic Coast Line. He declares that the cost of hauling by truck is naturally on the decrease since wages, gasoline, trucks and parts are declining in price. In discussing conditions in a territory surveyed by the Charleston & Western North Carolina Railway of the Southern System, Brand said:

"It fairly may be assumed that the trucks are going to handle a certain amount of cotton in the Carolinas regardless of rail-

### OSHKOSH DELIVERS "GROCERY STORES"

OSHKOSH, WIS., Oct. 31.—Four large "traveling grocery stores" have been built by the Oshkosh Motor Truck Co. and delivered under their own power to the U-Save-It Stores Corp. of Dayton, O., during the past week.

The cars were built on the standard four-wheel-drive chassis of the Oshkosh company and equipped with special bodies built by the J. L. Clark Mfg. Co. of Oshkosh. The Dayton company is conducting a "motor groceretaria" business, bringing a complete grocery store in miniature to the doors of housewives.

road freight rates, just as they are now doing as to freight traffic of all kinds as well as passenger traffic in sections along our lines traversed by improved highways. Trucks make warehouse delivery, which is of value, particularly as to small lots of cotton since drayage is avoided. A reduction in their rates may turn to the railroads some cotton now hauled by trucks, but the revenue derived from this additional cotton will not, as demonstrated by actual tests, already made for our line, affect the loss of revenue on cotton to interior mills alone.

"I do not believe that the interests of Southern cotton mills are adversely affected by the existing adjustment, nor that the producers of cotton will be benefited one iota by the reduction. A reduction in cotton rates will be an incentive to state commissions to bring about reductions in rates on other commodities, and will also be an invitation to shippers of other commodities to press for a general reduction in their rates."

(Continued on page 895)

### Erie Creditors Ask Collections on Stock

TOLEDO, Nov. 1.—A committee of the creditors of the Erie Tire & Rubber Co., Sandusky, has filed an application in Federal Court here asking for an order of the court compelling the receiver to collect unpaid portions of stock subscriptions.

The application states that there is due on preferred stock \$278,404, and on common stock, which was issued as bonus to purchasers of preferred, \$1,029,986.

There are claims of more than \$500,000 against the property and unless the unpaid portions of the stock subscriptions are paid the plant will have to be sold at a loss.

#### HINKLEY MOTORS SOLD

DETROIT, Nov. 2.—Property of the Hinkley Motors Corp. was sold at public auction to-day by the Security Trust Co. as trustee. The property includes equipment approximately valued at \$192,038; tool equipment valued at \$41,100 and stores valued at \$198,685. They will be offered in several parcels and also as a unit.

## British Truck Sales Await Trade Boom

### Impression Gained at Show is That Business Revival Must Come First

LONDON, Oct. 17 (By Mail).—Whether the British truck show will assist appreciably in lifting the truck industry out of the depression into which it has fallen in the past year remains a problem. The exposition itself has brought little in the way of actual sales and it is feared that until the general trade of the country revives there is not much hope that sales of commercial vehicles will increase to any extent.

There have been a good many inquiries for new motor coaches and omnibuses and firms which have a reputation for this type of vehicle, with a seating capacity of from 14 to 40, probably will pay their expenses and have something over. There also will be a few sales direct to the public of the smaller type of truck.

#### Many New Models

The proportion of new models at the show is surprisingly large and they are chiefly in the heaviest classes. In fact, trucks for bigger loads than ever before were suggested in England are among them. The Cadelon has a new model for 15,600 lb. net load while Maudslay has a new 13,500 lb. type with platform space 19 ft. 6 in. in length.

A half dozen makers are showing "overtypes" trucks having the driver alongside or over the engine. Four of these are new. Guy has a new 2800 lb. net load chassis which has attracted much attention both in its design and price, which is slightly less than \$2,000 and the lowest price high class British job of this kind.

Prospects for the passenger car show are difficult to forecast. The mild weather may induce a buying tendency but unhappily there is so little money available for the running and maintenance of cars that heavy sales are not probable. It appears that big cars will be in small demand for a long time to come. The public believes there will be a further drop in prices before the year ends.

### South African Imports Decline During Year

NEW YORK, Oct. 31.—Automotive trade conditions in British South Africa are summed up as follows in a cablegram from the National Bank of South Africa, Ltd., Capetown, to its branch here:

"Motor cars: Market tendency is better, country districts displaying more interest and a fair number of sales has been effected."

The dispatch also states that custom figures for the first seven months of the year, ending with July, show a falling off in automobile imports of 4758.

## Factories Deny Canadian Rumors

### Paige and Liberty Not Consider- ing Assembly Plants—Hupp Marking Time

TORONTO, Oct. 31—Automobile business in Canada continues spotty. Companies which have made radical price reductions report excellent business. This applies to Canadian makes as well as imported lines. The general feeling is that next year will be good and 1923 excellent. The outlook of the average dealer is decidedly optimistic.

The air is full of rumors about American companies establishing Canadian factories. The passenger car companies included in this list are Liberty, Hupp and Paige. The International Harvester Co. has taken over a plant in Chatham and now produces International trucks there.

W. C. Durant has spent considerable of his time for the last two or three weeks in this city. Arrangements have been completed to go ahead with the Toronto plant and stock is being offered to the public. Durant Motors of Canada, Ltd., has not as yet decided whether to link up with A. L. Carron of Carron Brothers, Montreal, and take over their extensive munitions plant for export business.

It is understood that Durant personally favors this plan because it would keep the Toronto plant busy supplying parts to the assembling plant for export during slack seasons. Inasmuch as the plan affects Durant operations in the United States, the final decision is understood to rest with the board of directors.

#### Hupp to Build

DETROIT, Nov. 1—The Hupp Motor Car Corp. will erect a Canadian subsidiary plant in Windsor early in 1922 if the business outlook is regarded as favorable at that time. The company has acquired a site for a factory but will defer actual building operations until the time is considered ripe. Paige and Liberty are not considering Canadian assembling plants, they assert.

#### Vesta Looks Over Ground

MONTREAL, Nov. 1—Officials of the Vesta Battery Corp. of Chicago have been looking over plants and sites in Sherbrooke for the establishing of their Canadian branch factory. The reason given for the establishing of a Canadian plant is the increased Canadian and foreign demand for the batteries. Much of the company's export business from the United States will be carried on by their Canadian branch. The plant will start with 60 to 70 men with a pay roll of about \$1,500 per week. It is expected operations will start within a few months.

#### RECEIVERS FOR DISTRIBUTOR

BOSTON, Oct. 31—Judge Morton, in the United States District Court, has

appointed Edward A. Badol and Charles C. Barton as receivers under bonds of \$10,000 each for Hares Motors Co. of New England, Inc. The concern was petitioned into bankruptcy recently by three creditors with claims of \$8,000. A third receiver will be appointed later.

It is expected some plan will be worked out whereby the Locomobile company will regain possession of the big building on Commonwealth Avenue which it used as a branch until it was occupied by Hares Motors.

### Willys Pays 10 Per Cent of Maturing Bank Loans

NEW YORK, Nov. 1—The Willys-Overland Corp. yesterday paid off in cash 10 per cent of its maturing bank loans of \$18,000,000. The balance has been renewed for eight months. Bankers for the corporation say that the concern is in a comfortable cash position.

It is understood that entirely satisfactory progress is being made in the program for refinancing the Willys Corp. Details now are being worked out under which it is expected a banking syndicate headed by Kuhn, Loeb & Co. will underwrite a note issue of approximately \$20,000,000. Business of the subsidiary companies within the corporation is steadily increasing and has been in satisfactory volume for some time. There are unofficial reports that operations will be started in the near future in the huge new Chrysler plant at Elizabeth, N. J.

### Hartford Parts Sale Advised by Committee

NEW YORK, Oct. 31—The creditors' committee of the Hartford Automotive Parts Co., headed by A. E. Brion, has addressed a statement to creditors recommending the sale of the assets under the direction of the court. It is recommended that the committee be prepared to bid in the property for the purpose of operating it in the interest of the creditors until such time as it can be sold and converted into cash for distribution among them.

Claims deposited with the creditors' committee aggregate approximately \$500,000. The statement points out that this plan would not jeopardize the interests of the stockholders or prevent reorganization by them, for such a reorganization could be effected by purchase of the assets at any sale the court may order.

### Agents for Carbureter Given \$55,000 Damages

CHARLOTTE, N. C., Nov. 1—Damage in the sum of \$55,000 was awarded to the Southern Automatic Steam Carbureter Co. of Charlotte against the Automatic Steam Carbureter Co. of Chicago in Federal Court here. The Southern company asked for \$150,000. The Chicago concern will appeal from the decision.

## Studebaker Shows Gain for Quarter

### Profits Exceed Year Ago by \$976,407—Regular Dividends Declared

SOUTH BEND, IND., Nov. 1—The Studebaker Corp. to-day declared the regular quarterly dividends of 1% per cent each on its preferred and common stocks, both payable Dec. 1, stock record Nov. 10.

During the quarter ended Sept. 30 last the corporation showed net profits of \$3,263,201, as compared with \$2,286,794, an increase of \$976,407 over the same period of 1920. For the nine months ended Sept. 30 last net profits amounted to \$9,644,326, against \$9,765,851 in the same nine months of 1920, or a decrease of \$121,525.

The earnings statement for the quarter and nine months ended Sept. 30 compares as follows with the same period last year:

	1921	1920
Number cars sold.....	21,086	15,765
Sales and receipts.....	\$29,058,893	\$27,823,611
Net earnings.....	4,263,201	3,179,572
Reserve for federal tax.	1,000,000	892,777
Net profits.....	3,263,201	2,286,794
From Jan. 1:		
Cars sold.....	55,552	41,092
Sales and receipts.....	\$80,593,998	\$73,374,153
Net earnings.....	11,644,326	12,208,629
Reserve for federal tax.	2,000,000	2,442,777
Net profits.....	9,644,326	9,765,851

The profit and loss surplus as of Sept. 30 last stood at \$15,396,874, as compared with \$9,822,048 on Jan. 1, 1921, an increase of \$5,574,826; cash in banks and on hand, \$9,332,846, compared with \$4,226,234; inventories on the same date were \$20,594,985, against \$28,076,793 on Jan. 1 last, a decrease of \$7,481,808; total quick assets were \$41,491,167, against \$41,367,497, with current liabilities of but \$11,161,791, compared with \$16,337,164 on Jan. 1, 1921.

### Pierce-Arrow Officials Dine George M. Graham

BUFFALO, Oct. 29—Officers, representatives of the board of directors and executive heads of the sales and manufacturing departments of the Pierce-Arrow Motor Car Co. gathered at the Ellicott Club last evening to bid goodbye to George M. Graham, who has resigned from the company to become the vice-president of the Chandler Motor Car Co.

Robert O. Patten, truck sales manager, introduced the speakers, who included Col. George W. Mixter, president; Col. Charles Clifton, chairman of the board of directors; John F. Guider, chief of production; Myron E. Forbes, treasurer, and L. E. Corcoran, passenger car sales manager. Others at the table included Robert F. Coleman, Joseph C. Dudley, C. D. Cowles, T. J. O'Rourke, Fred C. Wells, E. F. Himmele, Charles Sheppy and Walter P. Cooke.

## G. M. Folder Gives Stockholders Data

They Are Informed That Every  
Sixth Motor Vehicle in Use Is  
Corporation Product

NEW YORK, Oct. 31—An interesting folder setting forth all the essential facts in reference to the various motor vehicles made by the General Motors Corp. are contained in a circular which is being mailed to stockholders with their dividend checks. The information includes the number of cylinders, wheel-base, weight and factory prices of all the models in the various lines together with the location of factories and distributors. A summary of prices of touring cars shows Chevrolet at \$525 and \$975; Buick at \$975 and \$1,525; Oakland at \$1,145; Oldsmobile at \$1,145, \$1,625 and \$1,735; Cadillac at \$3,790. It is significant that Scripps-Booth is not mentioned in the circular.

A letter addressed to the stockholders by President duPont states that one out of every six motor vehicles in use in the United States is a General Motors product. He points out that "members of the immediate family share in the profits from every sale."

"Employees and stockholders are potential missionaries for General Motors. The institution—and users of General Motors cars are word of mouth advertisers of the products General Motors sponsors," says duPont. "If each of the employees and stockholders would interest himself to the extent of helping to convert but one new buyer a year, sales would be 33 per cent greater and profits accordingly larger."

President duPont points out that there are 133,500 persons in the General Motors family. These include 68,000 stockholders, 53,000 employees and 12,500 dealers and distributors. Since 1909 the corporation has produced more than 2,000,000 passenger and commercial cars, of which approximately 72 per cent are now in use.

## Many American Cars Entered in Olympia

LONDON, Oct. 21 (*By Mail*)—Whatever the result of the approaching Olympia car show, interest is being manifested through a large entry list. The number of bona-fide car chassis, bodies, parts, tires and accessories, and exhibits in the marine section, will probably be 550.

American cars listed are the following makes: Willys-Knight and Overland; Dort, Hupmobile, Essex, Hudson, Paige, Nash, Packard, Dodge, Buick, Chevrolet, Oakland, Cadillac, Scripps-Booth, King, Owen-Magnetic, Moon, Alsace, Dixie-Flyer, Stanley, and possibly two makes assembled from imported American parts.

### DALLAS TRADE IMPROVES

DALLAS, Nov. 1—The actual retail sales of automobiles on the part of retail dealers in Dallas for the month of

October exceeded those of the preceding month from 10 to 15 per cent, according to statements of the various retailers in Dallas.

The retail dealers attribute this increase to three things:

First—Reduction in retail prices.

Second—Increased prices for cotton and grain which gave the farmers more money.

Third—The automobile show for sixteen days during the State Fair.

The dealers also claim that more advertising, better personal solicitation, more team work and generally increased activity contributed materially to the improved conditions in this section.

## Monthly Report Issued on Motorcycle Exports

WASHINGTON, Nov. 1—Compilation of motorcycle export figures for each month by countries has been undertaken by the Bureau of Foreign and Domestic Commerce. This is the first time such figures have been made public.

The new division has announced that figures will be made public each month. The figures for September include both the number of machines shipped to each country and their value. The figures follow:

Countries	Number	Dollars
Belgium .....	18	4,931
Denmark .....	1	200
Estonia .....	8	2,900
France .....	53	12,925
Greece .....	1	300
Italy .....	36	10,098
Netherlands .....	252	62,771
Poland and Danzig .....	1	271
Spain .....	54	15,310
Sweden .....	3	815
England .....	7	1,810
Ireland .....	1	150
Canada .....	68	4,796
Panama .....	4	1,063
Mexico .....	12	3,891
Jamaica .....	1	50
Trinidad and Tobago .....	3	1,250
Cuba .....	4	1,116
Dutch West Indies .....	1	344

British South Africa .....	4	1,141
Total .....	627	151,380

## First Haynes Tractor Put on Seiberling Farm

KOKOMO, IND., Oct. 31—The first tractor manufactured by the Haynes Tractor Co. will be placed on the farm of A. G. Seiberling, vice-president and general manager of the Haynes Automobile Co., for further tests. According to John Powell, manager of the tractor company, and designer of the new product, no other machines will be manufactured until the first tractor has been fully tested.

## N.A.C.C. Considers Contract Changes

Recommendations Made at N. A.  
D. A. Conference Presented  
to Directors

NEW YORK, Nov. 2—Recommendations for contract modifications which have been approved by a special committee of the National Automobile Chamber of Commerce after a series of conferences with representatives of the National Automobile Dealers Association, were submitted to directors of the N. A. C. C. at their monthly meeting here to-day. If the suggestions are approved by the directors they will be submitted to the individual manufacturers for such action as they see fit to take.

### To Discuss Used Cars

The conferences between the special committees representing the two organizations have been marked by a spirit of cordiality and an honest desire to cooperate in solving problems which affect both branches of the industry. The proposed contract changes are in no sense radical but they are designed to remove some of the causes of friction which have arisen in the past.

After the directors have taken action on the contract changes, they will spend the major portion of their time wrestling with the used car problem. The N. A. C. C. has undertaken a survey of the entire situation with the idea of improving conditions which have become serious not only for dealers but for manufacturers as well. After the field has been carefully studied and analyzed the directors will make recommendations to improve conditions and also recommendations designed to aid in averting a repetition of a similar situation in the future.

### Hold Dealers at Fault

It is recognized that part of the present trouble is due to over production in the past but it is held that dealers also are somewhat at fault because they have accepted cars in trade-ins when it was not actually necessary to do so. Information is being gathered from all parts of the country as to the actual number of used cars remaining unsold and also full details of the most successful methods adopted in disposing of them. The N. A. C. C. knows that reports of a half million used cars on the market are greatly exaggerated. Although no definite figures are available at this time, it would not be surprising if the number did not exceed 350,000.

Many possible solutions of the problem are being submitted to the N. A. C. C. but most of them, if adopted, would be in restraint of trade. This is one of the most difficult elements in the situation because it will be impossible to take any stand which would cover the entire industry. Much valuable information in regard to successful selling plans is being received, however.

## Trade Associations Favored by Hoover

**States They Present an Indispensable Point of Contact With Government**

WASHINGTON, Oct. 29 — Although the Administration has declined to make a formal definition of its attitude regarding trade associations, pending the decision in the Memphis Hardwood case, an informal interpretation of its position is believed to have been expressed by Secretary of Commerce Hoover when he addressed the Synthetic Organic Chemical Manufacturers' Association here.

Secretary Hoover and Attorney General Daugherty have held a number of conferences on this subject and are understood to have reached an agreement on the general principles involved and apparently were on the point of making a public announcement. At the last moment, however, Mr. Daugherty is said to have come to the conclusion that it would have been injudicious to take such action, in view of the litigation now before the Supreme Court. Mr. Hoover reiterated his past position in support of the legitimate activities of the trade association, which he held to be not only "an enormous power in commerce, but a tremendous power for good in industry and it represents a new step in the whole social and economic development of our business lives."

### Co-operation Necessary

The various trade associations, Mr. Hoover said, present a point of contact for a department in the Government such as did not exist ten years ago, and by setting up a friendly relationship between the Department of Commerce and these associations, the Government is able to get in touch with the needs of all of the different branches of industry.

Mr. Hoover said he knew of no way by which it is possible to undertake the solution of collective questions relating to waste, adding as a preventive means, "except by the cooperative organization of the men in the industry; that we cannot go on and hope to make the progress that will maintain this standard of living in the face of the competition that we have in front of us, unless we can make some progress in the collective sense. So far as I know, the only way that we can hope for it is through the organization of associations that will take up the problems that are common to all, that gain inch by inch the efficiency and stability that make for national efficiency."

## Pierce-Arrow Deficit Increases Last Quarter

NEW YORK, Nov. 2—A report of the Pierce-Arrow Motor Car Co. for the quarter ended Sept. 30 shows a deficit of \$2,109,999 after charges, depreciation and Federal taxes. This compares with a deficit of \$1,400,550 in the previous quarter and surplus of \$355,310 in the

## SUPPORT GATHERING FOR SALES TAX PLAN

WASHINGTON, Nov. 2 — Senators who are advocates of some form of a sales tax declare they have almost enough votes to insure putting through one of three plans offered by Senator Smoot of Utah as a substitute for the miscellaneous excise taxes contained in the pending bill.

It is asserted that at least half the Republican membership is prepared to support the sales tax plan which has been advocated by the automotive industry. Party lines seem to have been obliterated in consideration of taxation measures. So many of the excise taxes already have been voted out that abolition of the remainder would result in the loss of a comparatively small amount of revenue.

corresponding quarter of 1920. The deficit for the nine months ended Sept. 30 amounted to \$4,000,051 compared with a surplus of \$1,778,354 for the corresponding period last year.

Directors of the company have set up a special reserve fund of \$3,750,000, which is considered ample to provide for shrinkage in inventories and other contingencies. It is stated that future statements of operating results will benefit from the adjustment which has been made.

## Republic Noteholders Asked for More Time

NEW YORK, Nov. 2 — The Republic Motor Truck Co. is mailing to noteholders to-day a request for an extension until 1926 on \$500,000 of its \$2,500,000 7 per cent serial notes which matured Nov. 1. The request is made because of business conditions, which have not permitted liquidation of sufficient inventories.

It was announced that a plan was in preparation, with the approval of the bankers, which provides for the payment of interest on the extended notes. The rate is to be increased to 8 per cent, it is said, and an adequate sinking fund will be provided. The same security will be given as under the present mortgage.

Confidence is expressed by the bankers that, with the extension plan adopted, the Republic company will be able to meet all its claims in full. It is understood that bank creditors have intimated their willingness to renew their loans.

In the balance sheet of Sept. 30, the company reports cash amounting to about \$500,000, the amount of the note instalment due. The bankers have refused to let this be withdrawn, since it would leave the company without working capital. Current assets total \$5,636,000 and current liabilities are about \$1,941,000, making a net working capital of \$3,695,000.

## Brighter Outlook Seen in Colombia

**One Company Handling American Lines Makes First Sales in Year**

BARRANQUILLA, COLOMBIA, Oct. 17 (By Mail)—Considerable improvement is under way here in regard to automobiles. One company, representing two American lines, sold a number of cars during August and September, the first they had sold since October of 1920. This improvement is due to generally better business conditions, to improved exchange and to the fact that Colombian products are moving in better volume. Further progress is expected.

Registration figures as of this date show that 332 automobiles and about 60 motor trucks are operating in the city of Barranquilla. Reports from Cartagena, another of the Colombian seaports not far from here, place the motor vehicles in that city as approximating 90 passenger cars, 20 trucks and 10 buses. The importations through Cartagena last year were 182 automobiles, five trucks and eight tractors. Several tractors are in use in the Cauca Valley near here and a number of the tracklaying type are employed in various parts of the country by the oil companies.

Among the recent automotive events of importance here was the organization of the Sociedad Automoviliaria de Colombia, composed of dealers and car owners, its object being the furtherance of automotive development and the promotion of rural highway and city pavement construction. The first meeting was held early in September and plans were made to cooperate actively with the Asociacion Automoviliaria de Bogota, which was formed some time ago in the Colombian capital with the same purposes as the Barranquilla organization.

## Dry Goods Association To Hear Fenn on Trucks

NEW YORK, Nov. 3—F. W. Fenn, secretary of the motor truck committee of the National Automobile Chamber of Commerce, will address members of the National Retail Dry Goods Association at a dinner at the Aldine Club in this city Nov. 9 on the use of motor trucks for short hauls. The attention of the dry goods dealers was centered on the use of trucks because of the railroad strike threat and Fenn will tell them something of their advantages.

The big difficulty in the past has been lack of insurance against theft. Merchants have lost large quantities of valuable merchandise in this way and they will insist upon adequate protection before resorting on a large scale to the use of the trucks.

Fenn addressed the woodland section of the American Pulp & Paper Association at Chicago last night on the increasing use of trucks in that industry.

## November Output to Meet October's

### Factories in Detroit Where Changes Have Been Made Expect Increase

DETROIT, Nov. 2—Production in the Detroit district in November will continue along the steady levels maintained in October, with a slight falling off looked for in some factories. In others where there have been decreased prices, new models and intensive selling efforts, gains are anticipated.

Medium priced cars have been most affected by price fluctuations, factories reporting a hesitancy on the part of dealers to do any stocking up. Despite this, sales are running strongly.

Ford Motor Co., with a production which will total approximately 85,000 in October, will manufacture about the same number in November, sales being reported as steady in all parts of the country with every indication that they will continue so. Revival in export business is having an important part in maintaining Ford's high production marks.

Packard has come through with a strong October business and expects to improve on this in November owing to lower prices on the single six line. A production of 10,000 of this model was planned to be reached by December of this year. With a month left this total is assured and will be exceeded. Enclosed models in the twin six line are reported sold six weeks in advance. November production in this line will approximate October's. Truck business in November will show an increase of 100 per cent over October, which had shown gains over previous months.

Cadillac is continuing on its high production schedule of its new models.

Lincoln reports an October business on a par with September, and has set a high schedule for November.

Roamer is continuing in strong demand and executives look for steady business for the rest of the year.

Hupp, with a price cut restoring 1917 levels, looks for heavy business in November after a somewhat dull October.

Buick and Studebaker continue to lead in their field, October business showing a slight decline, however, from the earlier heavy production marks. November will show a still further curtailment.

Reo reports business as steady and satisfactory.

Oldsmobile will continue along at about the October pace.

Hudson-Essex, with new models in the former and lower prices in the latter, report sales running high in comparison with earlier months.

Earl Motors has fixed a schedule for 500 of the new Earl in November, in addition to which it will manufacture Briscoe to meet sales in this former model.

Maxwell has not set a manufacturing schedule for its new line, but orders are

## October Car and Truck Shipments 96 Per Cent of Last Year; 11 Per Cent Below September, 1921

NEW YORK, Nov. 2—Reports of October shipments of passenger cars and trucks as compiled by the National Automobile Chamber of Commerce show that they aggregated 96 per cent of the total for the same month last year. It was the first month since the liquidation really got under way that shipments reached practically the same level as in the same period a year previous.

There is every reason to believe the comparison will be more favorable from now on. Gratification also is felt that October shipments showed a decline of only 11 per cent as compared with last month. Shipments for October of last year were 26 per cent less than for September. The shipment figures by months for this year and last follow:

	Carpools		Driveaways		Boat	
	1920	1921	1920	1921	1920	1921
January .....	25,057	6,485	29,283	3,185	....	93
February .....	25,505	9,986	43,719	7,507	....	99
March .....	29,326	16,287	57,273	9,939	....	75
April .....	17,147	20,187	64,634	14,197	....	1,619
May .....	21,977	18,608	74,286	15,193	....	2,381
June .....	22,516	20,269	60,746	18,834	8,350	3,947
July .....	23,082	19,470	52,342	15,320	8,702	3,725
August .....	23,286	20,350	34,060	14,290	7,095	3,565
September .....	20,804	20,150	24,431	13,550	5,469	3,580
October .....	17,209	17,323	14,127	11,257	2,519	2,300

reported running high and heavy business is looked for.

Dodge continued in October its schedule of 550 cars daily and is starting November on approximately the same schedule.

Dort will continue its October schedules.

Saxon reports business better than for several months and looks for steady November sales.

Columbia reports good October business and finds the November outlook satisfactory.

## Trucks Have Forced Lower Railroad Rates

(Continued from page 891)

The Atlantic Coast Line recently filed a petition pointing out that owing to competition, reduction in rates on cotton and cotton linters in the Carolina territory will have to be made in Georgia, Florida and Alabama, with the probability of the reductions extended clear into Texas. These statements indicate that the extension of highway systems throughout the South is the one great factor in motor-truck transportation. The railroads knowing that competition of motor trucks lessened on long hauls proposed to reduce the short haul and increase the long haul rates but the South Carolina Commission would not permit this action.

It is interesting to note that the railroads, especially the Atlantic Coast Line, believe that the truck competition can only be successfully maintained in cases in which the haul is not more than 50 miles, and then only in territories in which there are good roads.

There are many other commodities affected by motor truck transportation. Refineries have saved large sums by having their products hauled by motor trucks, which is made clear by railroads asking to reduce rates.

## W. R. Willett Heads Durant of Indiana

NEW YORK, Nov. 3—W. R. Willett, a veteran of the automotive industry, has been elected president and general manager of the Durant Motor Car Co. of Indiana, which will manufacture the six-cylinder Durant car in the former Sheridan factory at Muncie. A good share of Willett's business career has been spent with the General Motors Corporation. His latest work with that company was the organization of the Saginaw Products Co. division.

His apprenticeship in the industry was served in the Buick plant from 1904 to 1909. From 1909 to 1910 he was acting manager of the Rainier plant and later manager of the Welch Motor Car Co. at Pontiac for General Motors. He was works manager for the Gemmer Mfg. Co. of Detroit from 1913 to 1916, and later was general manager of the Chevrolet plant at Bay City, Mich. His first task will be to equip the Sheridan plant for the manufacture of the Durant six.

### 1,700,000 IN 1922

NEW YORK, Nov. 3—Careful estimates indicate that production of passenger cars and trucks for the calendar year 1921 will approximate 1,700,000 vehicles. This compares with 1,928,000 cars and 348,000 trucks, or a total of 2,276,000 for 1920. Inasmuch as it was predicted 1921 would be a "million car year" the output of motor vehicles has run far beyond expectations.

### ADAMS WITH RICKENBACKER

DETROIT, Nov. 3—Charles Adams has resigned as production manager of the Maxwell Motor Corp. to become production manager for the Rickenbacker Motor Car Co. Adams has long been closely associated with B. F. Everitt, president of the Rickenbacker company.

## Firestone Makes Price Reductions

Nothing Definite Decided by  
Goodyear or Goodrich to  
Meet Cuts

AKRON, Nov. 2—The Firestone Tire & Rubber Co. announced to-day that it had made a 20 per cent reduction in prices on cord tires, 10 per cent on fabric tires and 10 per cent on truck tires. This gives all tire purchasers the advantage of a 20 per cent discount offered to dealers some time ago effective until Oct. 31. The announcement evidences a sudden change of front by the Firestone company, which stated Monday that it did not contemplate continuing the 20 per cent discount which had been given to dealers.

It is considered probable that the other large tire manufacturers will be compelled to take similar action in order to meet competition, although there is said to be a possibility they may decide to let Firestone go it alone.

President E. G. Wilmer of the Goodyear Tire & Rubber Co., who declared Monday that he knew of no plan on the part of the larger tire companies to announce a general tire reduction, stated to-day that nothing definite had been done to meet the Firestone cut. A similar statement was made in behalf of the B. F. Goodrich company.

NEW YORK, Nov. 2—Tire companies with headquarters in this city are understood to be going over their schedules with the expectation of meeting the Firestone price cut but formal announcement will not be made until later in the week.

## Changed Maxwell Prices Accompany New Models

DETROIT, Oct. 31—Closely following its announcement of new models the Maxwell Motor Corp. announces it has revised its prices. The list follows:

	Old Price	New Price
Roadster .....	\$845	\$885
Touring car.....	845	885
Coupe .....	1,445	1,385
Sedan .....	1,545	1,485

President Wilson states that 24,000 cars on hand when the reorganization of the company was completed have been sold as well as nearly all the 10,000 produced since that time. Former models on hand now average less than one-half car per dealer.

### CHALMERS PRICES REDUCED

DETROIT, Nov. 1—The Chalmers Motor Car Co. has announced price reductions on its various models ranging from \$150 to \$400. The price revisions are as follows:

	Old Price	New Price
Roadster .....	\$1,495	\$1,245
5 passenger touring.....	1,545	1,295
7 passenger touring.....	1,795	1,395
Coupe .....	2,295	1,995

	Old Price	New Price
Sedan .....	\$2,445	\$2,295
Sport .....	1,695	1,445

### DAVIS PRICES CUT

RICHMOND, IND., Oct. 31—The George W. Davis Motor Car Co. has reduced prices on the sedan and coupé from \$2,795 to \$2,595. The price of the touring car was reduced early this month from \$1,895 to \$1,695. The latest reductions combined with the June revisions make total reductions from the December, 1920, prices of from \$455 to \$590.

## Tractor Manufacturers Make Price Revisions

CHICAGO, Oct. 31—The following reductions in the prices of tractors have been announced by the various manufacturers, effective immediately.

Name	Old Price	New Price
ARO .....	\$550	\$495
Aultman (22 to 45 rating) .....	3,850	3,420
Aultman (30 to 60 rating) .....	5,000	4,500
Caterpillar (25 rating) .....	4,250	3,975
Caterpillar (40 rating) .....	6,500	6,050
Centaur .....	405	385
Dart .....	2,100	1,800
Imperial .....	5,000	4,500
Kalumb .....	1,650	1,475
Peoria .....	1,785	1,600
Plowman .....	1,995	1,695
Port Huron .....	1,700	1,600
Allwork Model 2 G .....	1,875	1,775
Allwork Model 2 C .....	1,675	1,525

### NEW WILCOX PRICES

MINNEAPOLIS, Oct. 31—The Wilcox Trux, Inc., has made reduction in price on all its models as follows:

	Old Price	New Price
1 ton.....	\$2,100	\$1,900
1½ ton.....	2,775	2,550
2½ ton.....	3,300	3,000
3½ ton.....	4,250	3,950
5 ton.....	5,200	4,350

### TOWER REDUCES

ST. LOUIS, Oct. 31—The Tower Motor Truck Co. has reduced prices on its three models as follows:

	Old Price	New Price
1½ ton.....	\$3,000	\$2,900
2½ ton.....	3,475	3,200
3½ ton.....	4,400	4,100

### REPUBLIC LOWERED

ALMA, MICH., Oct. 31—Prices of Republic trucks has been reduced, effective immediately, as follows:

	Old Price	New Price
1 ton.....	\$1,695	\$1,395
1½ to 2 ton.....	2,295	1,795
2½ to 3 ton.....	2,795	2,195
3½ to 4 ton.....	3,845	3,095

### DOUGLASS TRUCKS REDUCED

OMAHA, Oct. 31—The Douglass Motors Corp. has reduced its 1½-ton truck from \$2,050 to \$1,850 and its 3-ton truck from \$3,250 to \$2,950.

### WALTER TRUCK CUT

NEW YORK, Oct. 31—The Walter Motor Truck Co. has reduced the price of its 5-ton model from \$5,600 to \$4,850.

## Committee Handles Mexico City Show

Twelve Dealers in Charge of  
Display Scheduled for  
Next Spring

NEW YORK, Nov. 1—Plans are now being made for the 1922 automobile show that will be held in Mexico City under the supervision of the automotive division of the American Chamber of Commerce of the Mexican capital. The show is to be held before the Mexican rainy season starts and after the New York and Chicago exhibitions, which, it is expected, will make it some time in March.

The show will be the second held in Mexico City, the first having taken place during April and May this year. The 1922 show, however, will be entirely different from the previous one, as it will be directed by a committee of automotive dealers of the capital and not by one man. The automotive division of the Chamber of Commerce, which was organized some months ago, plans to name a committee of 12 representatives who, through an executive committee, will be in charge of the show. The committee is to consist of six men representing the passenger car field and as many more representing trucks, tractors and accessories.

The preliminary plans, announced by S. L. Carrico, the Mexico City representative of the U. S. Rubber Co., provides for holding the show in the bull fight arena, a structure that affords ample exhibition facilities. Under the tiers of seats, Carrico explained, there are a number of large-sized rooms, connecting with each other and forming a large oval. These rooms will house the exhibits, the ring itself being reserved, if necessary, for the showing of heavy machinery, etc.

Automotive business throughout Mexico continues brisk, Carrico states, and, except for a possible seasonal decline, is expected to keep at a high pace.

### NO CHANGE IN DODGE OWNERS

DETROIT, Nov. 1—Directors of the Dodge Brothers Motor Car Co. announce that no change in ownership or management is contemplated and that the company has entered into long term contracts with F. J. Haynes, the president, and John Ballantyne, the treasurer, who will continue in charge.

### LOWER RAINIER PRICES

FLUSHING, Oct. 31—The Rainier Motor Corp. announces the following price revision on its trucks.

	Old Price	New Price
¾ ton.....	\$2,150	\$1,990
1 ton.....	2,350	2,150
1½ ton.....	2,600	2,490
2 ton.....	2,950	2,890
2½ ton.....	2,600	2,550
3½ ton.....	4,500	4,000
5 ton.....	5,250	5,100

## Finds Improvement in Latin-America

### Studebaker Representative Says Brazilian Market Offers Strongest Appeal

NEW YORK, Nov. 1.—Confidence in the future of the automotive trade between this country and Latin-America is expressed by M. C. Reichert, manager of the New York export branch of the Studebaker Corp. Reichert has just returned from an extensive trip to Argentina, Uruguay and Brazil, and he has noted already an extensive improvement in the general trade conditions affecting those three countries.

The Brazilian market made an especial appeal to the Studebaker representative, and he expects that the coming months and years will witness an impressive expansion in our sales to that country. This will take in not only the larger cities into which the American car has gone in great numbers, but also will concern the smaller cities both along the coast and inland. Reports of large stocks of automobiles and automotive equipment in the Brazilian ports were denied by Reichert who believes that the generally quoted statements concerning unclaimed cars in the various Latin-American centers are both misleading and exaggerated.

So far as Argentina is concerned, before his departure from Buenos Aires in late August, some fears were being expressed that the year's crops would be seriously damaged by lack of rain. However, since then reports have reached him of generous rains and the crop situation looks quite optimistic.

"All countries of Latin-America are proceeding rapidly and satisfactorily in assimilating the belief that the motor car is an essential vehicle of transportation needed in the upbuilding of their vast territories," he said. "There can be no doubt about the standing of the American-made motor car there."

"Competition from the European makers is more of a threat than an actuality, thus far having been almost entirely in the field of high-priced limousines and similar cars. Our activities in these countries are continuing without a let-up and we naturally have high hopes that this belief will be justified in continuing and increasing business."

## Trucks Led Federal Plan to Meet Strike

(Continued from page 888)

In the Middle West, Chicago was the mobilization center selected. It was not determined whether Washington or Pittsburgh would be the center for Maryland, Pennsylvania, Ohio, Virginia, West Virginia and Kentucky. Atlanta was selected as mobilization headquarters for the States of Tennessee, North Carolina, Mississippi, Alabama, Georgia, South Carolina, Florida and Louisiana. Kansas

City was chosen as the center for Nevada, Colorado, Kansas, Oklahoma, Missouri and Arkansas, while Houston was to be the point of mobilization for Texas and New Mexico.

For Arizona, California, Nebraska and Utah, San Francisco was selected as the central point. Seattle was chosen as the mobilization point for Idaho, Oregon and Washington, while Aberdeen or Pierre was decided upon for Montana, Wyoming, North and South Dakota.

The administrative section of the plan called for the assistance of governors and their State organizations in securing interstate movement of the supplemental necessities that they might require, and to set up relations with food and fuel industries to assist in interstate or inter-regional movements of supplies, and also to secure co-ordination of railway and water movement in the delivery of these necessities to points in need.

## Reeves Investigates Used Cars in Chicago

CHICAGO, Nov. 1.—Alfred Reeves, general manager of the National Automobile Chamber of Commerce, has been in this city for several days to attend the annual meeting of the National Association of Business Executives. Between sessions of this body, Reeves spent as much time as possible with Chicago dealers, inquiring into the used car situation. In explaining this activity, Reeves said:

"The Chamber is going into the used car phase of the automobile business very seriously. Our contact with the dealer's committee has brought us much excellent information and the members of the Chamber realize the seriousness of this situation more than ever before."

"My conversations with Chicago dealers have been very helpful to me. There is one peculiar phase to this question—it is as interesting and important to talk to a dealer who is troubled with his used cars as it is to talk to a dealer who is moving the used cars rapidly and making money from them. We need information on all points of this question."

"I have obtained some very helpful information from Chicago dealers, some of whom are quite advanced in this phase of the work."

## Louisiana Will Adopt Graduated License Tax

NEW ORLEANS, Nov. 1.—A graduated license tax on tonnage and a flat rate of 68 cents per horsepower on trucks and automobile buses has been agreed upon by a committee of the Louisiana Legislature in session at Baton Rouge. The license, which will be in addition to the 68 cents per horsepower, has been graduated as follows:

Trucks	Per Thousand
750 to 4,000 pound.....	\$10.00
4,001 to 5,000 pound.....	12.50
5,001 to 6,000 pound.....	15.00
6,001 to 8,000 pound.....	20.00
8,001 to 10,000 pound.....	25.00

The license proposed for auto buses would apply as follows: 1 to 7 passengers, \$2.50 per passenger; 8 to 20 passengers, \$3 per passenger.

## METAL MARKETS

LITTLE change is looked for in the market for those steels that enter chiefly into automotive construction until purchasing agents place their first orders for the 1922 season. That the last attempt to lift sheet prices to the extent of \$5 a ton proved an utter failure, should make for a conservative attitude in the matter of prices on the part of producers when 1922 demand sets in.

The market for strip steel is perhaps a shade steadier than it was, a condition, however, in no wise traceable to enlarged demand but solely to the fact that very little additional business for delivery before Dec. 31 is expected to be booked and that so far there is no chance to get any 1922 business on producers' books. Alloy steel makers have for so long been on short rations, as concerns orders from the automotive industries, that they will enthusiastically co-operate with prospective buyers and bring any possible sacrifice in order to broaden the outlet for their products.

Ferroalloys, moreover, have been liquidated with reference to price even more thoroughly than most other steel making raw materials. Nickel prices have been pruned likewise. All in all, if sellers show even the least sense of perspective, automotive buyers should be able to place 1922 orders, when the time for such contracts comes, without incurring the risk of driving prices upward to their own detriment, a danger that is always more or less present in seasonal buying by an entire industry.

What climbing aspirations pig iron values had, appear to have come in for a check due to the hesitancy of buyers to commit themselves until at least part of the 28 per cent freight rate cut on iron ores has been translated into price reductions on pig. In the steel industry, of course, the inability of the carriers to put into early effect further wage cuts which, in turn, precludes inclusive reductions in freight rates generally is being used as a convenient argument to explain the impossibility of further price reductions.

Pig iron.—Automotive foundries figure very little in the market, the majority having sufficient supplies on hand for present requirements.

Steel.—The sheet market remains at 3c. for black and 4c. for galvanized with blue annealed quoted at from 2.25c. upward. Full finished body sheets, 22 gage, are quotable at 4.35c. and upward. One of the low-priced passenger car builders continues to buy No. 9 gage tank steel quality sheets at the 1.75c. plate base price. Hot-rolled strip steel is relatively steady at 2.25c., with cold-rolled in light demand at from 3.75c. upward. Hot-rolled nickel steel (S. A. E. 2315-45) is nominally quotable at 4.50c.

Aluminum.—The new sheet prices of the domestic producer are still being cut by some of the importers of Swiss and German aluminum sheets. Quotations on the latter have ranged down to as low as 28c. for coils and 30c. for flats. Quite a few consumers, however, have been disappointed in the quality of some of these importations. British and French sheets are held on a parity with the domestic product. Somewhat higher prices are being asked for imported ingots by those who have them to offer.

Copper.—The market is once more pliable. There is talk of a resumption of production by the low-cost producers early next year.

## INDUSTRIAL NOTES

Robert H. Hassler, Inc., has broken ground for the seventh unit of its plant at Indianapolis. The new building will be two stories in height and will add 15,000 sq. ft. of floor space to the manufacturing facilities of the company. It will be completed in from thirty to sixty days. An eighth building, larger than that now under construction, is planned for erection next spring. The company is producing over 1000 sets of shock absorbers daily for all models of Ford and Dodge Brothers' cars.

Lincoln Motor Car Co. shipped 302 cars in September, the original estimate being 200. The shipments for October will aggregate 300. Third quarter shipments were approximately 600 cars compared with 850 the second quarter and 340 the first. The company is obtaining greater production with 2000 men than with twice that number a year ago. The greatest output now is in higher priced enclosed models, the November outlook indicating production of a minimum of 200 cars.

Federal Rubber Co. of Cudahy, Wis., division of the Fisk Rubber Co., has increased the rate of operations to approximately 65 per cent of capacity, and expects to be able to make further increases in the coming sixty days as the result of the steady demand for goods from all sections, enforced largely by prevailing low dealer's stocks. The number of men employed at present is nearly 1200, compared with a normal force of 1800 and a full capacity force of 2000.

Moon Motor Car Co. reports that its plant is working full time and that production is up to capacity. October production schedule was 100 per cent greater than the schedule for the corresponding month of last year, and this increased schedule will hold good for the next three months, it is stated, due to the amount of orders on hand. It is estimated that 85 per cent of the cars shipped were of the enclosed type.

P. & J. Motor Co., Inc., of Cudahy, Wis., which was incorporated recently with \$100,000 capital, is marketing an initial issue of \$50,000 to build and equip a machine shop for the manufacture of an air-cooled, three-cylinder engine, developing 29.7 hp. at a piston speed of 2000 ft. p.m. Dr. B. F. Palmer is president; George C. Dutcher, vice-president, and A. Dretzka, secretary and treasurer.

Hendee Mfg. Co. states that it has received orders for over 4000 motorcycles since new prices were announced Sept. 1. At the annual meeting of the company, Henry H. Skinner was re-elected president, and Frank J. Weschler, treasurer. It is announced that the working force has been increased since Sept. 15 from 450 to 900 men and that the goal of 1000 would soon be reached.

Cutler-Hammer Mfg. Co. of Milwaukee has completed a new sales arrangement with Brandenburg Bros. & Eccleston of Chicago, New York and Detroit, for the sale in the United States of the products of the Gear shift department of the Milwaukee company.

Glenwood Motor Car Corp., which will locate its plant at Findlay, Ohio, within a few weeks, has elected C. F. M. Niles, H. Fort Flowers and William A. Hollington, all of Findlay, directors.

American Chain Co. has removed its general sales and export offices to Bridgeport but will continue its district sales office in the Grand Central Terminal, New York.

Oakley Machine Tool Co. has moved its factory and general offices to Middletown.

Ohio, occupying part of the building of the Willard-Middletown Machine Co.

Root & Van Dervoort Corp. reports that the week ended Oct. 22 was the best in the company's history. New car orders actually entered totaled 48.

Niles-Bement-Pond Co. has obtained exclusive selling rights for the Cincinnati High-Speed Machine Co.

## FINANCIAL NOTES

Wright Aeronautical Corp. reports net sales of \$554,981 for the quarter ended Sept. 30. Net profits after reserve for taxes and including income from investments and patents amounted to \$214,935, equal to 98c. a share of the 224,390 shares of capital stock. For nine months to Sept. 30 net earnings after taxes amounted to \$1.91 a share on the stock. The total current debt is \$184,000. Working capital is in excess of \$2,000,000, this not taking into account a trust fund of approximately \$2,800,000 set aside for contingent liabilities of the old Wright-Martin.

Root & Van Dervoort Corp. balance sheet for Sept. 30 shows cash in hand \$81,913 against \$631,932 as of Dec. 31, 1920. Notes and accounts receivable on Sept. 30 were \$501,893 compared with \$896,361, Dec. 31. The inventories on the latter date totaled \$3,811,917 against \$1,571,630 on the date under comparison. Notes and accounts payable on Sept. 30 were \$2,889,698 and on Dec. 31, \$3,730,288. The surplus last December was \$1,466,792; in September they were \$880,384.

General Tire & Rubber Co. announces that the last of its bank indebtedness has been paid off. A year ago in May the debts aggregated \$2,000,000 which was \$500,000 in excess of capital and surplus combined. By November the indebtedness had been reduced to \$1,400,000. Sales for the present year, it is estimated, will be greater than for last year. The company has paid all dividends.

Fisk Rubber Co. combined income account for six months ended June 30, 1921, shows net income after depreciation and other charges, but before taxes, of \$1,856,268. The net sales were \$18,122,145; gross profit, after depreciation, \$6,156,255 and administrative, selling and general expenses, \$4,299,987.

B. F. Goodrich Co. has declared the regular quarterly dividend of \$1.75 a share on the preferred stock, payable Jan. 2 to stock of record Dec. 22.

Franklin Automobile Co. regular quarterly dividend of 1% per cent on preferred stock was paid on Nov. 1 to stockholders of record Oct. 20.

## DUPONT ISSUES STATEMENT

NEW YORK, Nov. 3.—The following statement in reference to rumors regarding the policies of the General Motors Corp. has been issued by President duPont:

"It is but natural that there should have been constant gossip during the past few weeks while automobile price revisions were under way. The policies of General Motors with respect to certain of its manufacturing divisions were not immune, the future of Oldsmobile being the subject of persistent rumor.

"This division is in a healthy condition with its business stabilized and sales increasing in the face of the coming winter. The present line of passenger and commercial cars, with gradual improvements, will be continued for 1922 and 1923 selling seasons. Thereafter new models as may be required by the trade may be introduced."

House Passes Road  
Conference ReportSenate Action Will Be Expedited  
Following Passage of  
Taxation Bill

WASHINGTON, Nov. 2.—By vote of 236 to 194 the House passed the conference report on the good roads bill. Every effort is being made to expedite passage in the Senate after the taxation bill is approved. However, it is expected that the anti-beer legislation will hold up enactment of the highway measure.

The principal opposition to the conference report was by Chairman Madden of the appropriations committee on the ground that it was sectional favoritism and extravagance.

The bill as passed by the House provides that the law shall be administered by the Department of Agriculture through the Bureau of Public Roads and not a commission. It also provides that the initiative in locating roads to receive Federal aid shall remain with the States. The several State highway departments, with the approval of the Department of Agriculture, shall lay out a system of roads, interstate and inter-county in character, and not interstate alone.

The funds from the several States put up to match Federal aid, from whatever source derived, shall be subject to the direct control of the highway departments of the several States.

The several States shall maintain and keep in good repair at all times all highways constructed with Federal aid. A penalty is provided for failure to put in proper repairs after 90 days' notice from the Department of Agriculture.

Open Meeting Arranged  
to Discuss Oil Status

NEW YORK, Nov. 2.—The rapidly failing supply of oil from Mexican sources, which for some years has been depended upon to fill the widening gap between American domestic production and consumption, has made it necessary to consider seriously the possibilities of securing supplies from other foreign sources.

Because of this situation, Ralph Arnold, chairman of the petroleum and gas committee of the American Institute of Mining Engineers, has arranged for an open meeting in this city, Dec. 13 and 14, 1921, at which foreign oil possibilities and related subjects will be considered.

Among those persons scheduled to speak at the meeting are Secretary of Commerce Herbert Hoover, T. G. O'Donnell, Henry L. Doherty, David White and Joseph E. Pogue. It is a significant fact that the meeting is to occur when the oil resources of the world are being discussed in connection with the Armament Limitation Conference at Washington.

Oil resources are regarded as having great international significance.

## MEN OF THE INDUSTRY

O. S. Tweedy and J. F. Lanier have become associated with the McKone Tire & Rubber Co. of Millersburg, Ohio, the former as general sales manager and the latter as southern distributor. Tweedy for many years was connected with the Diamond Rubber Co. and with the United States Tire Co. as general branch sales manager. Latterly he has been western sales manager of the C. Kenyon Co. Lanier was formerly associated with the Diamond Rubber Co., the Norwalk Tire & Rubber Co., and lately with the Howe Rubber Corp. as district manager.

F. M. Benson, formerly connected with the sales departments of the Chevrolet Motor Co. and the Sheridan Motor Car Co., has left the General Motors Corp. to organize the Benson Motor Car Co. of New York which will distribute Bell trucks in the eastern territory including New York and the New England states. The company will specialize in one-ton trucks and will build up a dealer organization throughout this territory.

L. W. Coppock, production manager of the Kalamazoo Motors Corp., has organized the Kalamazoo Tire & Rubber Co., Kalamazoo, Mich., which has taken over a portion of the building in that city formerly occupied by the Kalamazoo Steel Goods Co. The company will manufacture the Kalamazoo cord tire, one size only, 30x3½, and a production of 1000 tires a month is the scheduled output for the next few months.

Leland F. Goodspeed, for the past five years or more chief of the engineering staff of the Roamer, has resigned from the Barley Motor Car Co. to join forces with the Commonwealth Motors Co. of Chicago and Joliet, Ill. Goodspeed has been elected vice-president in charge of engineering of the Commonwealth company, which at the present time is working on a new passenger car model.

J. T. Knight, until recently district manager of the Kelly-Springfield company's branch in Atlanta, has been appointed southern district manager of the Howe Rubber Co. of New Brunswick, N. J., and Cleveland, Ohio, with southern offices and branch in Atlanta. A large warehouse will be opened here to take care of the company's business in the southern field.

Ralph W. Hollenbeck has been appointed special sales representative in the motor truck division of the International Harvester Co. For a number of years he has been auditor of the Springfield, Ohio, works. He will be succeeded at Springfield by Charles Miller. For the present Hollenbeck will cover the Ohio territory.

H. A. Kimber, formerly of the Quigley Furnace Specialties Co., is now in charge of the sales of the Quigley Pulverized Fuel Department of the Hardinge Co., New York City. This change was made owing to the acquirement by the Hardinge company of the pulverized fuel department of the Quigley company.

C. H. Hobbs has been appointed assistant general manager of sales of the Detroit Seamless Steel Tubes Co. of Detroit. For over fourteen years Hobbs was associated with the Lackawanna Steel Co. and for the last five years served as district representative in charge of the Detroit office.

Louis A. Pratt and Roy Moore have organized the Pratt-Moore Advertising Agency in Detroit with offices in the Ford Building. Both men are well known in the industry having been connected with the advertising

department of several important companies for a number of years.

William B. Hall, for the past four years in charge of General Motors Truck Co. advertising and other automotive accounts for the Green, Fulton, Cunningham Co., advertising agency, Detroit, has resigned to join the Dunlap-Ward Advertising Co. of Cleveland.

Robert I. Miner has been appointed sales engineer in the pressed steel division of the Motor Wheel Corp., Lansing. His activities will be devoted principally to handling the sales to car manufacturers of the Gier pressed steel plant of the corporation.

Fred W. A. Vesper, head of the Vesper-Bulck Co. of St. Louis, and treasurer of the National Automobile Dealers Association, will be elected this month president of the St. Louis Chamber of Commerce.

Joseph Husson, general sales and advertising manager of the Northway Motors Sales Co., Boston, has resigned from that position as of Nov. 1. His future connections have not yet been announced.

William N. Davis has rejoined Cadillac Motor Car Co. as body engineer, after having resigned from a similar position with Lincoln Motor Co.

Rolls-Royce of America  
Votes to Pass Dividend

SPRINGFIELD, MASS., Nov. 2—The directors of Rolls-Royce of America, Inc., have voted to pass the quarterly dividend of \$1.75 a share due preferred stockholders Nov. 1. As explained to the stockholders in a letter from L. J. Belnap, president, provision was made at the time of organization for such dividends during the period of construction, and an amount was set aside sufficient to pay five dividends.

Payments were made at regular intervals up to Aug. 1 last, from which date dividends on the stock became cumulative. In accordance with the schedule of operations, the statement goes on to say, the plant reached production May 1, and while earnings from that time have created a surplus, the directors do not deem it good judgment in view of the present depressed business conditions and in view of deferred charges during construction, to begin paying dividends at this time, but regular payments will begin as soon as the directors feel conditions justify it.

## CURTISS HEADS TIFFANY

NEWARK, N. J., Nov. 2—C. W. Curtiss, formerly general manager of the Splitdorf Electrical Co. and later president and general manager of the Van Sicklen Speedometer Co., until its sale to the Stewart-Warner Speedometer Corp., has taken a substantial interest in the Tiffany Mfg. Co. of this city, of which he has been elected president.

Associated with him are Paul J. Landemare, secretary and treasurer, formerly treasurer of the Splitdorf company and later controller of the Van Sicklen company, and Carl T. Mason, chief engineer, formerly chief engineer of the Splitdorf company. The Tiffany company manufactures a line of high grade automotive electrical specialties.

## BANK CREDITS

*Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.*

The fact that during the past week the United States Treasury was able to float a \$200,000,000 issue of certificates of indebtedness at 4¼ per cent and 4½ per cent, the lowest rates since the latter part of 1919, the issue being over-subscribed by \$400,000,000, is an indication of the general betterment of the credit situation. The week's local money market, however, showed signs of firmness. The range for call money was 5 per cent to 6 per cent, with 5½ per cent ruling, in comparison with 4 per cent to 5½ per cent the previous week.

The undertone for time money was also slightly firmer, and the rate for 60 and 90 day paper advanced to 5½ per cent, as compared with a range of 5¼ to 5½ per cent in the previous week. The quotation for the longer maturities up to six months advanced from a uniform rate of 5½ per cent to 5½-5¾ per cent. Prime commercial paper was in fairly good demand, with quotations maintained at 5½ per cent to 5¾ per cent.

Another outstanding event in the past week's market was the retirement by Great Britain of the amount still outstanding of the \$150,000,000 of 5½ per cent United Kingdom of Great Britain and Ireland Secured Loan of 1916.

The Federal Reserve System's statement for Oct. 28 furnished proof that the position of the banks is materially stronger. The total reserve ratio increased from 70.3 per cent to 70.8 per cent. Total gold reserves stood at \$2,786,239,000, an increase of \$13,518,000, and the highest of the year. Federal Reserve notes in circulation at \$2,408,779,000 showed a contraction of \$32,083,000. Total bills on hand decreased \$13,000,000, while total earning assets at \$1,562,021,000 marked a decrease of \$15,868,000, and a record low for the year, about 54 per cent below the peak figure reported for Oct. 15, 1920. Total deposits at \$1,738,556,000 increased \$21,112,000, of which \$15,504,000 was attributable to Government deposits.

A significant, although not unexpected, event in the industrial world last week was the calling off of the strike set for Oct. 30. Although the United States Steel Corporation's net earnings as reported for the quarter ended Sept. 30 were better than had been expected, they were insufficient to provide funds for the full dividends on the preferred stock. The net earnings of the Bethlehem Steel Corp. for the same period, on the other hand, were more than sufficient to meet dividend requirements of preferred and common stock.

## TRUCK CROSSES CONTINENT

NEW YORK, Nov. 1—A 5-6 ton pneumatic tired truck with six wheels, four of which are drivers, made a 3507-mile run from Los Angeles to New York in 6 days, 15 hours and 23 minutes

# Calendar

## SHOWS

- Nov. 14-19—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association, Fourth Regiment Armory.
- Nov. 27-Dec. 3—New York, Automobile Salon, Hotel Commodore.
- Jan. 28-Feb. 4—Chicago, Automobile Salon, Hotel Drake.
- Jan. 7-13—New York, National Automobile Show, Madison Central Palace, Auspices of N.A.C.C.
- Jan. 28-Feb. 4—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.
- Feb. 6 to 11—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.
- Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

- Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.
- Nov. 4-12—Car Show, Nov. 28-Dec. 3—Motorcycle Show.
- Nov. 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.
- Nov. 12-27—Buenos Aires, Annual Motor Show, La Pabellon de las Sosas, Automovil Club Argentino.
- Nov. 28-Dec. 3—Shanghai, China, Automobile Show.
- March, 1922—Santiago, Chili, Annual Automobile Show.
- May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibits in connection with the Brazilian Centenary As-sociao Automobilista Brasileira.

## CONVENTIONS

- Nov. 14-19—Chicago, Annual Meeting and Business Exhibit of Automotive Equipment Association.
- Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.
- Nov. 21-23—Atlanta, Third Annual Convention of American Farm Bureau Federation.
- Dec. 6-8—Chicago, Second Annual Meeting of American Petroleum Institute.
- Dec. 10—New York, American Institute of Mining and Metallurgical Engineers.

Dec. 20—Philadelphia, American Society of Mechanical Engineers.

Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.

Jan. 17-20, 1922—Chicago, American Road Builders Association.

Jan. 30-31—Chicago, Fifth Annual Convention, N. A. D. A., La Salle Hotel.

June 11-15—Milwaukee, Annual International Convention of the Associated Advertising Clubs of the World.

Sept. 18-23, 1922—Rome, Italy, Second Annual Meeting of the International Chamber of Commerce.

## S. A. E. MEETINGS

- Detroit, Nov. 18, Dec. 23, Feb. 24, March 24, April 28, May 26.
- New York, Jan. 11-14, 1922—Annual Meeting.
- Chicago, Feb. 1
- Minneapolis, Feb. 8—Tractor Meeting.

## Australasian Trade Shows Improvement

### Automobile Imports During First Half of Year Made Notable Increase

LOS ANGELES, Nov. 3—Latest reports received here from the automotive trades in the Australasian markets indicate that business conditions are appreciably improving.

Despite the distressing conditions prevailing in Australia and New Zealand during this year, the American automobile trade has not suffered to any large extent. As a matter of fact, the latest official statistics reaching here show that in some instances automobile imports have increased over the first half of 1920.

In the 1920-21 fiscal year, Australia imported motor chassis valued at \$4,093,108, as compared with total imports of motor chassis in the 1919-20 fiscal year amounting to \$2,443,189, or an increase of \$1,649,919. These statistics emphasize the remarkable development of the body building trades in Australia, which have been greatly encouraged by the high Australian tariff on imported bodies. As against the figures showing the imports of motor chassis the following statistics showing the imports of motor bodies stand in significant contrast: 1920-21 fiscal year, \$194,719; 1919-20 fiscal year, \$137,165, showing an increase of \$57,554.

The total trade of the Commonwealth of Australia in the 1920-21 fiscal year amounted to \$295,258,620, as compared with \$248,797,801.

In New Zealand there has been a slight falling off in the imports of motor vehicles this year as compared with 1920. The total value of automobiles imported by New Zealand in the seven months ending July 31, 1921, aggregated \$1,022,391, as compared with \$1,499,801 in the same

period of 1920 and \$434,224 in the same period of 1919.

Under pressure of the government and the banks the import trade of New Zealand has been greatly restricted during the last few months. In fact, the total import trade for July was almost back to the pre-war level.

## Automotive Merger Waits All Stockholders' Assent

NEW YORK, Nov. 1—Incorporators of the Associated Motor Industries which, it was announced last week, would take over the Jackson Motors Corp., do not contemplate making public the details of the merger, which will take in 19 automotive companies with assets of approximately \$65,000,000, until early in January.

It is explained that while the officers of the various corporations which will be included have signed contracts, it will be necessary to obtain the consent of a majority of the stockholders in each corporation. Satisfactory progress is being made in this work but inasmuch as there are several hundred stockholders in some of the companies it will require a considerable period to complete the negotiations.

## Cadillac Adopts Plan to Aid Used Car Sales

DETROIT, Nov. 1—The Cadillac Motor Car Co. is undertaking to assist dealers in handling used car sales through the establishment of a used car exchange of ideas which will be handled through the advertising department. Ideas of Cadillac dealers who are meeting the used car problem successfully in creating demand will be gathered into a brochure which will be distributed to all Cadillac dealers.

Copy and layouts for advertisements will be prepared in the advertising department and will be mailed to dealers.

## Price Factor Leads in Peruvian Trade

### Improvement in Exchange Accomplishes Reductions and Stimulates Business

LIMA, PERU, Oct. 17—The predominant note in the automotive market in Peru lately has been the lowering of prices. This is revealed in the advertisements appearing in the daily press. When prices began to fall in the United States a year ago, merchants here were prevented from reducing prices for two reasons: First, there was an unfavorable turn in the exchange, the fall in the value of the Peruvian currency more than counterbalancing the fall in price abroad; second, the Peruvian Government raised the tariff rate on automotive products. For these two reasons, when prices were falling in the States, Peruvian merchants instead of reducing prices were compelled to advance them, much to the bewilderment of their customers.

More notable than either the sale of automobiles or tractors in Peru is the increasing use of trucks. The light one-ton truck or ¾-ton is selling better than the bigger trucks, though these are also becoming more numerous. The Peruvian Post Office Department has recently put in service several Albion (Scotch) trucks to haul mail.

## BUYS WILCOX MOTORS' ASSETS

MINNEAPOLIS, Oct. 31—The Wilcox Trux, Inc., has acquired the interest of F. E. Satterlee as receiver of the H. E. Wilcox Motor Co. by purchase of the assets of the receivership. All future business in connection with the manufacturing, sale and service of Wilcox trucks will be handled by the new corporation at its offices 1030 Marshal Street, N. E., Minneapolis.

## ATWATER KENT

*Ignition, Starting and Lighting*

Atwater Kent development has kept pace with and frequently anticipated the rapidly changing needs of the automotive industry.

From the beginning of this business almost twenty years ago, a policy of "quality first" has been maintained.

*The result:* appreciation in the shape of hundreds of thousands of factory equipped touring cars, trucks, motor boats, tractors and stationary engines, every one giving that enduring satisfaction that goes with merchandise of quality.

ATWATER KENT MFG. COMPANY

*Philadelphia*

Red-blooded VIRILITY vitalizes the entire Continental organization. It energizes every Continental undertaking. Unconquerable, it drives ahead, bridging the gaps between ideals and realities, converting the motor dreams of today into the Red Seal qualities of tomorrow. ¶ The automotive industry knows and feels this VIRILITY—relies upon it to co-operate forcefully in advancing transportation

standards. ¶ And, since this quality—VIRILITY—is so active within the Continental organization, necessarily it is hereditary in the Continental product. Daily it may be sensed in the performance of the Red Seal motor—the motor that cloaks intense aggressiveness in a dignity of silence—the motor that bears on its crankcase a world renowned insignia of excellence—the Continental Red Seal.

## New Small Cars Feature British Automobile Show

Attendance is good and optimism prevails at British car show. Many price drops precede opening. Number of chassis model increase. Small cars feature exhibition. 40 more exhibitors than last year.

By M. W. Bourdon

LONDON, Nov. 5 (*Special Cable*).

**T**HE fifteenth annual London show was opened yesterday at Olympia and the White City, the two buildings which have been used for the exhibition in recent years. It is yet too early to take a measure of the prospects for 1922, but hopefulness and almost optimism prevails on many stands, despite the fact that there has been so far no appreciable recovery in other industries. The majority of the exhibitors are cheered by dealers' reports and by their greater readiness than last year to discuss contracts, especially for cars of under 150 cu. in. displacement.

There has been an increased interest in all-weather bodies. This type has to some extent usurped the position as favorite held by coupes and sedans at this show last year. The British exhibits in general have high-grade body finish and carry excellent accessories. There is a large display of polished chassis and parts.

British dealers are exhibiting an increased interest in service features of the new models. They are critical of chassis layouts from the standpoint of accessibility, and are examining the new jobs carefully from the service angle.

On the first two days the attendance was good; being approximately the same as last year, but not equal to the 1919 crowds. For this the division be-

tween Olympia and the White City is partly responsible. Visitors again, to a certain extent, neglect the section at the White City, placing exhibitors there at a great disadvantage. The White City section has more variety and interest, however, in several ways. One admission fee is good for both sections, and free transportation is furnished. Marine engines and motor boats are also shown in one of the White City buildings.

There are 563 stands at the show, including accessories exhibits, and 43 stands of a marine character. This represents an increase of 40 stands over last year. Six hundred and eighty cars of 145 different makes are shown on 190 stands. Fifty of these stands belong to body builders. Of British makes there are 78; French, 34; American, 18; Italian, 9; Belgian, 3; Swiss, 2; Dutch, 1. American cars at the White City are the Essex, Moon, Dixie, Hudson, Stanley, Paige, Dodge, Alsace, King and Packard. At Olympia are the Hupmobile, Dort, Buick, Chevrolet, Oakland, Nash, Overland and Cadillac. By the regulations, concerns in financial difficulties are kept out of the show and, consequently, the Angus Sanderson, Austin, Bean and Sizaire-Berwick are not represented.

The prices of most British cars have been considerably reduced, and several announcements of price cuts were made just prior to the show, because the

Left—Horizontal water-cooled twin cylinder engine ( $3\frac{1}{2} \times 3\frac{3}{4}$  in.) of new 7 hp. Wolseley. Has battery ignition. Upper right—New B.S.A. chassis with air-cooled overhead valve two-cylinder engine ( $3\frac{1}{2} \times 3\frac{3}{4}$ ). Lower right—New 10 hp. Singer ( $3\frac{1}{2} \times 3\frac{3}{4}$  in.) four-cylinder with three-speed gearset as unit with front end of torque tube instead of with rear axle as hitherto

new rules prohibit price changes during the show period. The biggest drop since last year has been in the price of the 12-hp. Morris, two-passenger; two cuts were made aggregating 30 per cent, the present price being £300. The 8-hp. Rover was reduced 27 per cent. This reduction was made in three steps, and the present price is £220. Other cars have been reduced in price since the last show by the following percentages: Daimler and Vauxhall, 25; Sunbeam and Standard, 20; Rolls-Royce, 16; Wolseley, 15; Lanchester, 12; Humber, 10. Enfield, Austin, Napier and Cubitt have made no reductions. The Cubitt "16" is still the lowest priced full-size British car, selling at £440.

Many makers have increased the number of their chassis models. The Daimler Motor Company has a new "20," which gives this firm three distinct models. Armstrong-Siddeley has added two new models, and Wolseley one, the latter company now producing four models. Sunbeam, Vauxhall and Star have each added one model and now have three each. Vulcan and Talbot have added two models each and now have four. Singer, Austin, Standard and Belsize have one model more each, giving them two each. All additions are entirely distinct models, with few parts that are not of special design or size. No British maker of luxury cars has discontinued that type.

Some exhibitors affirm that the number of genuine private inquiries at the show was distinctly encouraging. Lanchester, Rolls-Royce, Napier and Leyland are still specializing in expensive models. The Rolls-Royce "4," regarding which there have been some rumors, has not made its appearance, nor will officials of the company make a definite statement concerning it. But three new "fours" supplement the Guy "8."

The outstanding feature of the show is the number of new small cars. Cars of this type are exhibited by 20 different makers, of which 11 are French and 9 British. This class includes water-cooled, four-cylinder cars of less than 70 cu. in. piston displacement. In many

cases two- or four-passenger bodies are optional. Two-cylinder models of similar size, but mostly with air-cooled engines, are exhibited by 17 British and one French manufacturer. These are all two-passenger models. The number of chassis models with a piston displacement of between 70 and 100 cu. in. and designed for four-passenger bodies has also increased, this model often being furnished with a fixed or detachable type of sedan body.

The new chassis of 15 hp. and over include two of the Guy additions, the Vulcan "20" with new split-sleeve valve, the Daimler "20," the Armstrong-Siddeley "18," and the Singer and AC sixes, both of which have cylinder dimensions of  $2\frac{1}{2} \times 4$  in. The Entz electric transmission appears on two of the British cars exhibited—the Crown "6-30" with a Knight engine and the Magnetic "4-16" with Argyll sleeve-valve engine. Information is given out that the Magnetic will also be manufactured in a straight eight model, but this is not exhibited.

Production on the Phoenix "18," which was exhibited at Olympia last year, is beginning only now, the delay having been due to trade conditions and not to any faults in the design. Straker-Squire is reintroducing in a slightly modified form its pre-war 15-hp. chassis to supplement the post-war overhead-camshaft, six-cylinder model.

Disregarding the two-cylinder models, the following percentages apply to individual models of all nationalities: Four-cylinder chassis, 76 per cent; six-cylinder, 17 per cent; eight-cylinder, 5 per cent; twelve-cylinder, 2 per cent. Detachable heads are found on 58 per cent of the models exhibited, side valves on 64 per cent, overhead valves with pushrods on 17 per cent, overhead camshafts on 12 per cent, sleeve valves on 7 per cent. Pressure lubrication is found on 61 per cent of all models, magneto ignition is used on 77 per cent, vacuum feed on 58 per cent. Unit power plants are incorporated in 43 per cent of the chassis models, cone clutches are

found on 46 per cent and dry single-plate clutches on 31 per cent, while the remainder have multi-plate clutches which are about equally divided between the dry and wet types. Fifty-one per cent of the models have four speed gearsets, 48 per cent have the Hotchkiss drive, on 67 per cent the final drive is by spiral bevel gears and on 13 per cent it is by worm. Both brakes are located on the rear wheels in 51 per cent of all models, while in 39 per cent one set is on the rear wheels and the other on the transmission, and front brakes are fitted in 10 per cent. Wire-wheel equipment is supplied on 29 per cent of the models, disc wheel on 28 per cent, hollow-spoked metal wheels on 26 per cent and wood wheels on 17 per cent.

British design does not show any definite trend in respect to change in cylinder number, except that there is an increase in the proportion of two-cylinder models. The four-cylinder models still represent 77 per cent of the whole. The number of sixes has increased, but this increase is so slight that the percentage represented by them is smaller than last year. There has been a decrease in the proportion of side-valve engines from 72 to 66 per cent, whereas the overhead-valve type of engine has advanced in representation from 21 to 24 per cent. Of these overhead-valve engines 56 per cent have pushrods at the side of the cylinders. There has been a decrease in the use of straight-toothed spur gears for the camshaft drive from 23 to 18 per cent, while helical spur gear drives decreased from 31 to 22 per cent.

As regards cooling practice, circulation by pump and by thermo-siphon action are still used on substantially equal numbers of models. Radiator shells of white metal, not plated, show a large increase, being now found on 31 per cent of all models, as compared with

5 per cent last year. Separate shells for the radiator are exceptional. Aluminum pistons are found on 33 per cent of the models, an increase of 7 per cent since last year. The representation of pressure lubrication has increased to 57 per cent. Magneto ignition is still fitted on 94 per cent of all of the models, while of the new models 20 per cent have battery ignition.

Of the 24 new chassis models, ten have unit power plant construction; on seven the transmission gear is mounted amidships, on five the gearset is built in a unit with a torque tube and on two it is combined with the rear axle. Cone clutches have decreased from 61 to 52 per cent, while single-plate clutches have increased from 27 to 34 per cent. The representation of four-speed gear-boxes has gone up from 50 to 58 per cent. Hotchkiss drive is now used on 46 per cent of the models, the same as last year, while fabric universal joints show a further increase, from 28 to 40 per cent. The representation of spiral bevel gear drive has also gone up, from 46 to 53 per cent. The practice of making both brakes of the internal type and locating them on the rear wheels is now represented in 67 per cent of the models, as compared with 61 per cent last year. There are only four models shown which have external brakes.

Quarter-elliptic springs are more popular than last year, being shown on 20 per cent of the models as compared with 16. Floating cantilever springs have made no further progress, being still found on 22 per cent of the models. Hollow-spoked steel wheels have dropped behind, being shown only on 48 per cent of the models as compared with 56 per cent. On the other hand, the representation of the disk wheel has increased to 29 per cent, while the wood wheel representation remains the same, at 5 per cent. All of the wheels are detachable.

1—New 14 hp. overhead valve Sunbeam ( $2\frac{1}{2} \times 4 \frac{3}{4}$  in.) with standard four-passenger body. 2—New 7 hp. Wolseley two-cylinder runabout; high-class job selling at approximately \$1,500. 3—Four-passenger 11 hp. Beardmore. Engine has overhead camshaft with bore and stroke  $2\frac{1}{2} \times 4\frac{1}{2}$  in. 4—New 20 hp. four-cylinder Daimler with sedan coupe body having folding rear quarter. 5—New 11 hp. Humber ( $2\frac{1}{2} \times 4\frac{3}{4}$  in.) four-passenger sedan

No British car maker is as yet supplying straight-side tires as standard equipment, although several may do so when their present stocks of wheels are reduced.

No British car now in production is equipped with front wheel brakes, nor is there any apparent demand for such brakes. Cables are more extensively used for brake operation than heretofore. Several new aluminum axles are shown, and there are three new aluminum engines. The new Vauxhall four-cylinder engine, which is of the L-head type, has iron cylinders and an aluminum head, the cylinder dimensions being 3 by 5½ in. It forms a unit power plant with a three-speed gear-box. Ignition is by magneto, and the rear axle is of aluminum construction. Fitted with a four-passenger body, this model is priced at £750.

The two continued Sunbeam models, the "4-16" and "6-24," both have the new overhead-valve engines with pushrods on the sides, the cylinder dimensions being the same and the chassis design unaltered. The new four of the Sunbeam company has overhead valves and aluminum cylinders with steel liners, the cylinder dimensions being 72 by 120 mm. (2.84 x 4.73 in.). Among the features of this model are unit power plant construction, a three-speed gearset and battery ignition. The four-passenger model sells at £725.

On the four-cylinder, 11-hp., overhead-valve model of the Standard the engine and chassis dimensions have been increased. This company has also introduced a new four-cylinder model with a 67 cu. in. overhead-valve

engine. This model is furnished with a mechanical seat starter and with either a two- or four-passenger body. The price is £340. A new six has been added to the Armstrong-Siddeley line, supplementing the 30-hp. model. It is of substantially the same design as the latter, with small modifications in details, the cylinder dimensions being 2¾ by 4½ in. The price is £800.

The new Singer is the smallest British six-cylinder car, the cylinder dimensions being 65 by 100 mm. (2.56 x 3.94 in.). It sells for £675. The new Wolseley four-passenger model has a two-cylinder, water-cooled, horizontal opposed engine of 58 cu. in. piston displacement. It is a high-grade job, with mechanical seat starter, and is priced at £315. Daimler interests are represented in the B. S. A. concern which has brought out a two-passenger car with air-cooled, 90 deg. V-type engine of 65 cu. in. piston displacement. This model is equipped with an electric starter and is priced at £340, but it compares poorly with the Rover "8" at £220, despite its somewhat better equipment.

Armstrong-Siddeley have developed a new model—not shown at Olympia nor as yet in production—which is fitted with an air-cooled, two-cylinder, 90 deg. V engine, an inverted clover-leaf body and a central steering column. This model is to sell at £225. Many other makers set out to produce a car that should compete with the Rover, but none of the models that have matured seriously threatens what is almost a monopoly in a big, new market.

## German Trials of Aluminum Pistons

**E**ARLY the present year the German Department for Aerial and Motor Vehicle Transport organized a competition for aluminum, or, rather, light alloy pistons, in which three cash prizes of 10,000, 6,000 and 4,000 marks were offered. The results of this contest have just been announced, the first prize having been awarded to the Griesheim-Electron Chemical Works for an alloy consisting of 87 per cent magnesium and 13 per cent copper; the second prize to Karl Schmitz, for an alloy of aluminum and copper cast in metal molds, and the third prize also to the Griesheim-Electron Chemical Works for an alloy of 88 per cent magnesium and 12 per cent aluminum.

All tests in connection with the contest were made at the Motor Vehicle Laboratory of the Berlin Technical College. Nine different firms had entered 32 sets of pistons made out of 16 different alloys. These were tested in a 10-30 hp. passenger car engine and a 45 hp. truck engine. In addition to dynamometer tests, tests were made of the heat conductivities of the alloys and of their capacity for heat absorption, these latter tests being made in an electric oven specially designed for the purpose, which could be heated to 570 deg. Fahr. These tests were made both on the new pistons and on pistons that had gone through the dynamometer tests.

In the endurance tests in the dynamometer laboratory it was endeavored to determine the best compression ratio, by gradually increasing this ratio and refitting the pistons. These tests lead to the conclusion that for the truck as well as the passenger car engine a compression ratio of 5.7:1 was the best, both as regards power output and fuel economy. With this ratio the truck engine developed an average of 21 per cent more power than with gray iron pistons and consumed 20 per cent less fuel per horsepower-hour. In the case of the passenger car engine the gain in output was only 5 per cent and the saving in fuel 13 per cent, as this engine

was of the L-head type and had a very flat compression space. As a result of the higher efficiency of the aluminum pistons, the temperature of the exhaust gases was reduced when these pistons were used. Thus in the case of the truck engine the exhaust temperature dropped from 1340 to 1030 deg. Fahr., and in the case of the passenger car engine, from 1140 to 936 deg. Fahr. The heat carried off by the cooling water was reduced 20 per cent in the case of the passenger car engine and 35 per cent in the case of the truck engine, on the basis of the horsepower-hour.

An economy in the consumption of lubricating oil of 50 per cent was also secured. The explanation is that with cast iron pistons the oil burns on the piston and is then unavailable for lubricating purposes. If rather contrary results have been obtained in practice, this is probably due to the fact that the aluminum pistons are generally not fitted as accurately as in these tests. There is also the possibility that extreme changes in load have an unfavorable influence on the oil consumption. It was proved by the experiments that the required clearances are not nearly as great as has generally been assumed heretofore. The clearance required is 0.0025 D to 0.003 D on the skirt and 0.005 D on the head for aluminum pistons, as compared with 0.002 D on the skirt and 0.0025 D on the head of cast iron pistons, D being the cylinder bore.

Tests regarding the thermal properties showed that the thermal conductivity is materially reduced by carbon deposits on the cylinder head, which explains why in an engine with carbonized cylinders a good deal of trouble is experienced from pre-ignition. As carbon does not adhere well to the heads of aluminum pistons, this type of piston is also advantageous from this point of view.

It was shown that the friction load does not increase if aluminum pistons are substituted for cast iron pistons.

# Engineering Features of British Trucks at the Olympia Show

The "over-type," affording bigger loading platform on the same wheel-base, is increasing in popularity. Heavier load units are in evidence. Largest four-wheeled chassis now carries 15,500 lb., plus 6,000 lb. on a trailer. Considerable attention given to passenger-carrying vehicles.

FROM a spectacular point of view the British Commercial Motor Show held at Olympia, October 14-22, must be considered an advance on any previous exhibition of this kind; potential buyers—of whom there were comparatively few ready to place orders at once—had a wider range for selection in both chassis and bodywork, and the show was impressive in making clear the ever-widening scope of motor transport.

The most prominent feature was the large amount of attention given by exhibitors to passenger-carrying vehicles; some most elaborate examples of saloon and all-season motor coaches were staged, and it is safe to say that 80 per cent of the orders booked were for passenger-carriers, though Guy claimed to have booked up two-thirds of next year's output of his new 2750-lb. model and to be quite satisfied with prospects of larger types.

There was not quite the same air of pessimism in regard to business prospects as at last year's show, but, on the other hand, the real optimists were few, and those that existed were for the most part concerned with light and fast delivery wagons for loads up to 3500 lb. or so. The general depression of industry hung over all, and it was fully realized that the truck business cannot improve materially until trade all around revives. As a result, truck makers refused even to make a rough estimate of their production for 1922, for in nearly all cases they will work "from hand to mouth," erecting a dozen or two chassis at a time and waiting

until those are on the way to absorption before getting to work on another batch.

Prices have fallen materially in a number of cases, and Dennis, one of the leading firms, made a cut amounting to over 20 per cent just before the opening of the show. But this reduction was exceptional, and 7½ to 10 per cent represents the usual.

Not a great number of new models of British trucks have been introduced since last year, and these recent introductions possess so many individual features that they afford of themselves very small indication of the general trend of British design. With the exception of one or two private car firms, which have put forward slightly modified chassis for industrial purposes, no British maker has introduced a new delivery van chassis intended for loads of less than 2000 lb. Cubitt is one of the passenger car people who have entered the truck sphere with a modified car chassis for loads up to 1600 lb.; this is the cheapest British van of its type, and yet the chassis price is approximately \$2,000 (normal exchange).

Next in order of load-carrying capacity among the new models is a distinctly interesting production of Guy Motors; it has a maximum net load capacity of 2750 lb. and is excellent value in England at the price at which it is offered, viz., just under \$2,000 (£395). Unlike the Cubitt, it is primarily designed for solid tires with a chassis weight of only 2800 lb.; but pneumatics are offered, and recommended, at \$100 extra. This refusal

Scammell six-wheeler with furniture van body measuring 27 ft. 6 in. x 7 ft. 6 in.

Left side of Hallford engine

Right side of Hallford engine

of British truck makers—for it amounts to that—to design a chassis primarily for pneumatic tires is still general. Even in the case of public service passenger vehicles, in connection with which the use of pneumatic tires is rapidly increasing, no British firm has yet come out with anything beyond a slightly modified truck chassis quite suitable for running on solids.

This reluctance to design for pneumatic tires may be put down to two causes. In the first place, there is no denying that 1921 has been an extremely bad year for British truck makers, a fact which is not only due to the general depression of trade, but also to the large number of surplus army trucks of various sizes which have been offered at prices far below those applying to new chassis. As a result of this depression in the truck industry the majority of makers have found themselves short of funds and almost entirely unable to secure additional capital; so that, even though some may have felt inclined to embark on a new model or a new range of models suited only and primarily for pneumatic tires, they have found themselves in a position preventing any such enterprise.

The second reason is conservatism. Even where capital has been available for developing new types of chassis of lighter construction and otherwise specially designed for pneumatic tires it has been felt that until the demand for such vehicles assumes far bigger proportions than at present it is better to "play for safety" and offer chassis made for solid tires to those buyers who intend to fit the alternative.

Goodyear has done a great deal of propaganda work in respect of giant pneumatics and has been successful to a limited extent in making sales to owners of motor coaches seating from 16 to 28 passengers. But even those members of the truck industry who have had experience of pneumatics are by no means satisfied that the giant pattern is so good as moderately sized twin pneumatics on the rear wheels, and one sees quite as many, if not more, pneumatic-tired passenger vehicles of the capacity just mentioned with twin tires as with giants.

As for trucks of over 4000 lb. load capacity with pneumatic tires of either kind, it is rarely, indeed, that one is seen on roads where an almost continuous stream of long-distance truck traffic occurs. In the big centers of population, such as London, Manchester, Glasgow, etc., pneumatic-tired trucks—used mainly for local delivery of loads up to 4000 lb.—are by no means rare, and at a rough estimate comprise 25 to 30 per cent of the total number.

In two respects British truck design in the larger sizes is moving toward affording greater load capacities. In the first place, four additional firms have in some of their models moved the driver's position forward so that he is either alongside or over the engine. In three cases the same wheelbase and overall length of the hitherto largest model are retained, but a bigger platform area for the load is secured by the variation, and, usually with an engine of larger dimensions, the chassis is made capable of coping with heavier loads. At present the Caledon 7-tonner (15,500-lb. load capacity) is the biggest British truck in respect of net load, and this is put forward by its makers as suitable for hauling, in addition, a trailer with 6,600 lb. aboard. The Caledon, incidentally, is one of the three British truck chassis using sleeve valve engines. In this particular case the Burt and McCullum (Argyll) single-sleeve engine is used, with a bore and stroke of 4 5/16 x 5 1/2 in.—distinctly on the small side for loads such as those mentioned.

There is but little doubt that the Caledon policy and that of other firms catering to the demand for bigger load units is justified, for not only is the number of trucks with trailers attached to be seen on the roads rapidly increasing, but the Scammell 6-wheeler (combined tractor and trailer) is securing appreciable favor, and has in this way justified itself within 12 months of its introduction. Up till now it is the only combination of the kind on the British market.

#### Engine Design

As might be expected at the present stage of truck development, and particularly in view of the state of the industry of late, no very marked deviation in engine design is apparent. With regard to cylinder construction, for example, the L-head type still predominates, and no additions have been made during the year to the overhead valve construction, except in a new Maudslay model. T-head cylinders are not yet defunct, and one of the best known of British makers (Dennis) only 12 months ago introduced a new model with this valve arrangement.

Four cylinders are used in practically all cases, there still being only one maker using a six-cylinder motor, and even this maker, who at last year's show came forward with a one-model-only (six-cylinder) program, has resurrected two of his earlier four-cylinder types, obviously on account of finding his market restricted by the policy adopted 12 months ago.

Integral heads for the cylinders are not quite so

numerous as last year, for the detachable variety now comprise 24 per cent of the total instead of the 20 per cent 12 months ago. To a similar extent the block casting for four cylinders has increased, and there are now for the first time two examples of a cylinder block cast as a unit with the top half of the crankcase, on the 1600-lb. Cubitt and the 11,000-lb. Straker Squire.

#### Camshaft Drive

Of the overhead valve engines used for trucks 60 per cent have the camshaft overhead; one example has bevel gearing at the top and bottom of the vertical drive shaft, while the remainder have helical pinions at these points. Camshafts within the crankcase for both side valves and push-rod operated overhead valves are mostly driven by helical gearing, though the silent chain drive is not far behind, the percentages being, respectively, 42 and 33; 21 per cent have straight pinions, and the remainder have a form of worm drive.

#### Water Cooling

The vast majority of truck engines of all sizes have pump water circulation, though among the 14 per cent with thermo-syphon are some of those with large load capacity. Even a new 13,000-lb. truck (Commer) depends upon natural flow. But by no means have all the circulating pumps a positive drive, for 30 per cent are operated by a link V-shaped belt, which, in a few instances, also serves to drive the radiator fan on the same shaft as the pump rotor.

This question of water circulation is exercising the minds of some of those firms which are thinking of designing new models in the near future. The thermo-syphon, 13,000-lb. truck referred to, and a few others of slightly smaller capacity, have proved that this simple and inexpensive system is quite practicable for industrial vehicles, and, that being so, a few designers are asking themselves why they should go to the expense of applying a pump to future models. Not a few makers have already, it would seem, put this question to themselves, and have adopted a compromise, apparently in fear of over-heating troubles if they went the whole way and used the plain thermo-syphon system. The compromise in question consists of designing the water jackets, connecting pipes and radiator for natural circulation and then supplementing this with a belt-driven

water "accelerator," which, while admittedly less efficient than the usual pump, does not impede a natural flow if the belt becomes detached or so stretched as to be hopelessly inefficient. But, like all compromises, it does not go all the way in either direction. It saves very little in cost as compared with a positively driven pump, and has not the advantage of thermo-syphon of eliminating an item which cannot fail to require periodical attention and be subject to wear.

Vertical finned-tube radiators with aluminum tanks are almost general, there being only 8 per cent with plain tubes and 6 per cent of the cellular type. Only one maker has horizontal tubes and only two have other than aluminum casings, one using cast iron and the other sheet brass.

#### Engine Mountings

Unit powerplant construction hardly exists in British truck practice, there being only three examples of this put forward by two makers. The most favored methods of mounting the engine are (1) by the three-point system with the engine arms directly attached to the main frame, and (2) by the use of a sub-frame to which the crankcase is secured at four points. Forty per cent of engines have the first-mentioned arrangement and 39 per cent the second. The sub-frames themselves are almost equally divided between three- and four-point suspension systems.

Several chassis with sub-frames have the latter connected to the main frame at three points, though the makers do not go so far as Guy in providing a spherical bearing at the front and two spherically ended swinging suspension links at the rear. In regard to this Guy practice in the maker's largest model, it is of interest to note that it is not continued in a modified and slightly smaller type, which has a four-point suspended sub-frame, nor in an entirely new model, which has something approaching a three-point inflexible suspension in the main frame. Another feature of note in connection with this same make is that for the first time a truck maker with internal-combustion-engined vehicles has introduced an electric model—one of three new Guy trucks at Olympia being a 2½-ton (5600-lb.) electric.

Cast iron still remains the usual material for truck engine pistons, only 7 per cent being of aluminum. The straight-sided-type piston is also in a vast majority,

Powerplant of Thornycroft 4,500-lb. truck. The engine has overhead inlet valves. Central gear shift lever is a new feature

Rear end of 4½ x 6-in. overhead camshaft Maudslay engine

Water jacketed Karrier induction pipe with transverse passages at inner ends of cylinder pairs

Thornycroft belt-driven water pump at front of cylinder block, extension of pump shaft driving the fan

though 10 per cent of trucks have the hour-glass design in cast iron. Three compression rings are usual, though in nine examples there are four rings to each piston, and in one example two only. A scraper ring in the skirt occurs in 49 per cent of pistons, though among the remainder the majority have the lower compression ring groove beveled off with small holes drilled through to the interior.

Methods of securing the piston pin have not varied appreciably, for with the exception of 13 per cent fixed in the small end of the rod and 15 per cent floating in small end and piston, all have the pin secured by set-screws, bolts or split-pins in the piston bosses.

#### Engine Lubrication

As is the case in car practice, hollow shaft lubrication is making headway, 43 per cent of crankshafts being drilled to convey the lubricant to main and big-end bearings; but in only three engines is a full-pressure system adopted, and piston pin lubrication in other cases is maintained by splash. The simple trough system with oil pockets over the main and camshaft bearings is losing ground, and its place is being taken by a trough and pressure system in which splash from the troughs is depended upon only for the big-ends and cylinders, direct leads being taken from the pressure circuit to the main journal and camshaft bearings.

#### Carbureters and Vaporization

The Zenith carbureter is by far the most popular among British trucks, some 64 per cent having this device, but only one unusual system is in evidence with a view to securing better vaporization. This is found on Hallford trucks. With these engines, which have pair-cast, L-head cylinders—the valves on the left and the Zenith carbureter on the right—a big hot-air muff is cast integral with the exhaust manifold; leading from the muff a copper air pipe passes between the cylinder blocks to a jacket around the vertical portion of the induction manifold on the right side, and from this jacket a U-shaped pipe leads into the main air inlet of the carbureter, which has a rotating sleeve with ports for admitting and regulating a cold air supply. Thus the air at a high temperature passes at first through the induc-

tion manifold jacket and, leaving it at a reduced temperature, enters the carbureter.

This engine, too, is peculiar in having a "balance" pipe to correct or modify the gas pulsations. From the branched induction pipe on the right the gas passes through a passage in each cylinder block to the central inlet ports on the left, and connecting the left side of the passages in the two blocks is a flanged and bolted-on aluminum pipe of the same internal diameter. This arrangement is claimed to prevent deposition of the fuel, to enhance economy, increase the power developed and provide much smoother running.

A hot-air muff or a water-jacketed induction manifold is the usual arrangement to assist vaporization, integral or adjacent inlet and exhaust branches being exceptional. Gasoline is the standard truck fuel, only one manufacturer making a point of offering a kerosene vaporizer.

Throttle governors are standard on 31 per cent of engines, optional on 20 per cent, and cannot be fitted to the remainder.

#### Fuel Feed

Gravity feed for the carbureter with the tank under the driving seat is the usual combination in fuel feed and tank location; the vacuum system has made no headway, occurring on only four chassis, the same as last year. Of the remainder only three are other than of the gravity system. Some 24 per cent of chassis have the fuel tank mounted on the rear of the dashboard, as compared with 68 per cent under the seat. Maudslay in a new model has adopted an unusual tank position, suspending it from the right-hand member of the frame with a vacuum system of feed.

#### Electric Equipment

The magneto is universal on chassis designed for truck work only, the Cubitt van already mentioned alone having a battery system of ignition. In 14 per cent of cases the ignition timing by the magneto contact breaker is fixed. Impulse starters are standard on 8 per cent of engines, the makers will not fit them on 69 per cent, while on the remainder they can be provided as an extra. Electric lighting is standard in only two chassis, though it is being fairly widely adopted by users, and all except two British truck firms will fit it as an extra to the normal chassis price. Engine starters are conspicuous by their absence.

#### Crankshaft and Camshaft Bearings

As might be expected, the vast majority of crankshafts have three main bearings, this number being used in the only six-cylinder engine as well as in most of the fours. Straker Squire, however, uses two roller bearings only in a block-cast, four-cylinder engine with the upper half of the crankcase forming a unit with the cylinder block. Maudslay uses five plain bearings in two models, though the largest and most recently introduced type has three. Albion also has two engines with five crankshaft bearings.

Ninety per cent of crankshaft journals are plain white metal-lined shells. Straker is the only user of roller bearings for this purpose, and Commer trucks—four models in all—have the only engines with ball bearings,

a feature which has been embodied in this make since Commers were introduced in 1906.

Three bearings for the camshaft is also the usual number, these being of phosphor bronze in 80 per cent of cases, but Tilling-Stevens and Commer in five and four models, respectively, use ball and plain bearings for the camshaft. In the former there are three ball bearings within the actual crankcase and an additional one in front of the distribution gear; Commer uses two ball bearings, one at each end and a plain bearing in the center. Another variation from the normal is in one of the A. E. C. models, where the camshaft runs in a central roller bearing and two plain bearings, one at each end.

### Transmission Bearings

Ball bearings are almost universal for gearsets, though 10 per cent have the roller type for both main shaft and layshaft and 8 per cent make use of plain bearings. The pilot bearing is also more frequently of the ball type, 45 per cent of gearsets being thus provided; 35 per cent of pilot bearings are, however, plain bushes, 7 per cent are roller, while the remaining 13 per cent are floating phosphor bronze bushes.

### Wheel and Axle Bearings

The floating bush still remains the most popular type for wheel bearings, some 55 per cent of the front wheels and 45 per cent of the rear axles having this type. Plain, non-rotating bushes are used in 18 per cent of front wheels and in 24 per cent of rear axles, while roller bearings are preferred as an anti-friction type to the ball variety at both points.

At the differential ball bearings are, however, in the great majority, 84 per cent of rear axles being thus equipped, as compared with 14 per cent roller and only 2 per cent plain.

The foregoing remarks concerning truck bearings can, therefore, be summarized as follows: Plain bearings for the crankshaft, ball bearings for the gearset, floating bushes for the wheels and ball bearings for the differential represent the predominant practice.

### Clutch Design

The cone clutch continues to predominate on British trucks, for although it has given way slightly to the dry single plate, there are still 76 per cent of vehicles having it in one form or another, as compared with 79 per cent at this time last year. The inverted cone appears on only 14 per cent of the total of 76 per cent just mentioned. The remaining clutches are all of the dry single-plate pattern, with one exception, which is a dry multi-plate. Leather facings for cone clutches are still found on 25 per cent of trucks, but the use of fabric is very general, though Churchill, on a 7000-lb. truck, retains a metal-to-metal cone pattern running in oil.

### Universal Joints

In the connection between clutch and separate gearsets the fabric disk is gaining ground, but, nevertheless, metallic joints are used at this point in 62 per cent of

Tire pump on Daimler chassis driven from rear end of layshaft in gearbox

Cast cross member supporting front end of Karrier truck engine

British trucks. This majority comprises quite a large variety of types, though the most popular is the pot or sliding block pattern, accompanied by some other type which does not allow for a sliding motion. Steel disks in place of fabric are used in 10 per cent of clutch shaft joints and leather rings in 9 per cent, Thornycroft being one well-known maker who favors the leather ring joint in place of the fabric disk. An accompaniment of the latter frequently observed and arranged at the front end of the shaft to give the necessary sliding motion, is an internally toothed ring engaging with teeth formed on a boss at the front end of the shaft. These teeth are cut like those of a straight pinion, but are an easy fit in the toothed ring and thus allow a limited amount of universal movement.

For propeller shafts the star or Hooke's joint is most generally used at the front end, and a sliding block or pot joint at the rear when the shaft is open, though 21 per cent of open propeller shafts have a star joint also at the rear end. Two makers—Daimler and Dennis—use ball bearings for this type of universal joint, though in the latter make it is confined to one model only, a recently introduced 4500 lb. type.

Fabric disk joints for the propeller shaft have not made any headway of late, representing only 10 per cent of the total, a percentage which is exceeded by the leather ring type which is seen in 12 per cent, including Thornycroft's. The internal toothed ring joint mentioned in connection with clutch shafts is used by Commer on one model with a semi-enclosed propeller shaft, this form of coupling being located at the front end of the shaft which forms the front and open half of the propeller shaft behind the gearset.

### Final Drive

The top worm for the final drive has increased slightly at the expense of the side chain and now appears on 53 per cent of trucks. Only one truck has the bottom worm, namely, the 7000-lb. A. E. C. chassis, which is intended primarily for buses and motor coaches. The A. E. C. is made by the Associated Equipment Company, the makers of 95 per cent of the London buses.

There are no internal gear-driven British truck chassis and only 20 per cent have a double reduction by bevel and spur gearing. One maker has introduced an unusual double reduction system. This appears on the Pagefield 9000-lb. truck designed specially for export, and includes worm and spur gearing in the rear axle, the first reduction being by a top worm. It is claimed

Cross member for Dennis torque tube supported by rubber bushes in frame brackets

Cast tubular cross member supporting spherical front end of Karrier torque tube

as an advantage for this arrangement that it gives an extremely big ground clearance at the axle center. Where the propeller shaft is open the Hotchkiss system is fairly general.

### Brakes

With the exception of the Cubitt converted chassis, no British truck has external wheel brakes. Seventy-five per cent have the pedal applying to a transmission brake and the lever operating internal expanding brakes on the wheels. Nineteen per cent have both sets in the wheel drums and 6 per cent have the pedal brake on the final drive shaft and the hand brake on the wheels.

The usual type of external brake located behind the gearset is of the locomotive pattern with cast ribbed shoes lined with fabric segments and linked together at the operating ends by levers. Cam action is used rarely. Where there are two expanding sets in the wheel drums they are arranged side by side.

### Springs and Wheels

The half elliptic spring is practically universal, there being only two trucks with other types at the rear, one

having a three-quarter elliptic and the other a cantilever. The latter has its rear springs duplicated, one unit of each pair of full cantilever springs being above the other with a trunnion bearing between them at the center and the axle between them at the back.

At last year's Olympia Show it appeared as though the hollow spoked cast steel wheel was on the way to becoming universal, but since then it has fallen back slightly and now appears on 49 per cent instead of 55 per cent of trucks. The disk type has also receded (12 per cent against 21 per cent), but the webbed cast steel pattern has gone ahead and now represents 21 per cent of the total. Wood wheels are used with two chassis, the Churchill truck previously mentioned and the Beardmore 1800-lb. van.

### Rear Axles

The two most popular types of rear axles are (1) the banjo forging arranged horizontally, with an aluminum sump and an aluminum or cast steel top section carrying the worm gearing and differential as a unit (or double-reduction gearing if it is used) and (2) the cast steel casing with a large top opening for the gearing

Method of operating Thornycroft transmission brake and adjustment for worm shaft

Brake coupling yokes of Straker truck and flat steel connections to rear wheel brakes

Front wheel brake connections and support on Burford motor coach chassis

mounted as in the other case. Axles are almost invariably of the full floating type, the wheel bearings being mounted on the banjo extensions when the center is a forging. When the center is cast various forms of extensions are used; in some cases the latter are flanged

and bolted on to the ends of the center piece, but in as many others the center has integral extensions for the wheel bearings, while some have seamless steel tube extensions to carry the bearings, the tube being shrunk into the main casing.

## Refinements in Design Feature New Air Compressor

**A** NEW air compressor designed for car and other similar applications is shown in the accompanying cuts. It does not depart from conventional design in most particulars, but certain refinements in detail are said to render it unusually efficient and to make it more durable than other similar equipment.

The cylinder, which is made from very close grain cast iron to prevent porosity, has a bore of  $1\frac{3}{4}$  in. and is  $3\frac{1}{16}$  in. long from the bottom of the flange to the under side of the cylinder head, which, like the top of the piston, is machined perfectly flat. The outside of the cylinder is provided with circumferential ribs which are machined all over and brought to a sharp edge. The cylinder head is cast integral and is machined to receive the valves which seat directly in it. The valve guides have long bearing surfaces, and the valves are inclosed by screw caps which are slightly undercut at the seat to form a sharp edge, which cuts into the cylinder metal when the cap is screwed home and thus forms a tight joint without gaskets.

The valves are made of Monel metal and are of the automatic poppet type. The inlet valve has a solid stem and is returned to its seat by a light, coiled spring. The exhaust valve is hollow and is necked at its lower end above the seat. The spring fits loosely into the hollow barrel of the valve and is kept cool and lubricated by oil which partially fills the opening inside the barrel.

The piston is of cast iron and has but one ring groove into which are fitted two concentric rings, each of which are made slightly elliptical when free, but are said to form perfect circles with uniform pressure at all points when in place in piston and cylinder bore. The outer ring is said to be made of semi-steel cast flat and rolled up after the ends have been trimmed to form a stepped joint. The joint on the inner ring is made at an angle

in more conventional fashion and is placed at 180 deg. from the joint in the outer ring.

The crankpin is overhung, being integral with the flange at the end of the crankshaft. A split connecting rod bearing is therefore not required. All connecting rod and crank bushings are of liberal proportions and made of bronze.

The compressor has a stroke of  $1\frac{1}{2}$  in. and can be run, it is claimed, at speeds as high as 3000 r.p.m. It will pump to pressures in excess of 400 lb. and is therefore capable of inflating easily even the largest pneumatic tires used in truck service. Lubrication is effected by Gredag, with which the crankcase is filled, and there is said to be no leakage of lubricant past the piston. H. E. Pelletier, who is responsible for the design and development work, states that he has run one compressor continuously for nine months, pumping against a pressure of 50 to 100 lb., and that there was no carbon or other deposit on the cylinder, piston head or valves at the conclusion of the test, also that there was no appreciable wear on any part.

The crankcase of the compressor can be made from cast iron or aluminum, as desired, and is furnished with a gear drive for application to standard gearbox flange, or in removable unit with connections and support for attachment to the front of a car with drive direct from the crankshaft of the engine. It is also made up in a portable unit with  $\frac{1}{3}$  hp., 1800 r.p.m. electric motor driving the compressor through a 2-to-1 gear or chain reduction.

**T**HE rural schools in the United States operate 12,000 motor vehicles transporting children to and from school.

# Wills Sainte Claire Car Has Engine of Original Design

Has been in production for several months, but engineering and production features have never previously been made public in detail. Drive of overhead camshaft is an unusual feature, as is the automatic fan release in the cooling system. Departures from conventional design are noted.

By J. Edward Schipper

**A**LTHOUGH the Wills Sainte Claire car has been in production since March, and just prior to that time a few of the general specifications of the car were printed, the trade has never had the opportunity of studying the engineering and production features in detail. In this article AUTOMOTIVE INDUSTRIES presents for the first time the details of construction. The car is noted for its many departures from conventional practice, particularly in the engine and in the body design and equipment.

An interesting feature in connection with the design of the engine is that it has been worked out by a man who, as chief engineer and production manager of a company noted for its extremely large production of a low-priced car, naturally has had the problem of low-cost production continuously in mind. At the same time, the engine has been designed as a high-class unit in which the utmost has been done to secure smoothness and good performance. The use of eight cylinders and overhead camshafts demonstrates this clearly. The combination of the two objects in design—that is, of quality of performance and economy of production—makes this engine worthy of close study.

In the arrangement of the cylinder block a 60-deg. angle has been adopted for balancing reasons. This arrangement gives a radial, rotating resultant inertia force of constant magnitude, as opposed to a horizontal, reciprocating resultant inertia force in the 90-deg. V eight-cylinder engine. In other words, the cross vibrations for which 90-deg. eights are noted are eliminated with the 60-deg. angle.

## A Solid Head Engine

While an exterior view of the engine gives the appearance of a detachable head, this is in reality a solid head engine with a detachable camshaft housing. The tops of the cylinder blocks are machined flat to form a seat for this housing. The intake manifold is cast integral with the cylinder block and surrounded by water, and the exhaust manifold is a separate casting bolted to the cylinder block. A little kink in design which is interesting is the fact that the top and bottom piston rings overlap the cylinder bore in the top and bottom dead center position. This is done to keep the cylinder bore smooth and to avoid the formation of rings, due to wear. The cylinder bore is beveled at the bottom to facilitate slipping the cylinder blocks over the pistons. The lower part of the cylinder barrels extends down into the upper crankcase to reduce the overall height of the engine. Each cylinder block is held down by studs screwed into the upper crankcase.

In common with other engines recently developed, the combustion chamber in the Wills Sainte Claire engine is highly polished to prevent the formation of carbon. It has been found that by the elimination of dead corners and rough spots deposition of carbon is prevented from starting.

A question that arises in connection with the solid head type of engine is in regard to difficulty in grinding the valves. It is claimed that it is easier to grind the valves on this particular solid head engine than on a detachable head engine, because it takes no longer to remove the block from the crankcase than it does to remove the ordinary type of detachable head because the same number of nuts and cap screws are used. With the detachable blocks the grinding operation can be performed on a bench, and this makes it readily possible to thoroughly clean the blocks after grinding.

The cast iron pistons are a light-weight type with flat, polished heads. Three rings are used, two being placed above and the other below the piston pin. The piston pin is hollow and held in the piston boss by a set screw.

In accordance with usual practice for eight-cylinder engines, the articulated type of connecting rods is used. The connecting rods, both forked and plain, are of H section and machined all over. The inside of the bronze connecting rod bearing is babbitted, the bearing being accurately machined to size and requiring no scraping or fitting.

The crankshaft, like all other parts of the car which are highly stressed, is of molybdenum steel. The shaft is carried on three main bearings, the dimensions of which are given in the tabulation herewith. The caps are held to the upper part of the crankcase by two through-bolts to each bearing. In bearing replacement the entire bearing is changed, the two halves being machined to close limits for fit and interchangeability.

## Overhead Camshaft Drive

One of the unusual features of the engine is the drive of the overhead camshafts. From the crankshaft there is a drive by spiral bevel gear and pinion to an intermediate shaft, and spiral bevel gears and inclined shaft take the drive from this shaft to the two overhead camshafts. Inserted in the drive is an Oldham coupling with offset driving lugs, so that it is impossible to reassemble the camshaft driving members incorrectly and thus disturb the timing of the engine. The camshafts are molybdenum steel, and each camshaft is carried on three plain bearings, the rear bearing being of special design to eliminate noise due to unsteady rotation of the camshaft.

Plan view of Wills Sainte Claire chassis

Details of fan and  
generator shaft  
drive

This variation in rotative speed of the camshaft is a source of noise and wear. During the opening period of the valves the valve spring pressure tends to retard the motion of the camshaft, while during the closing period it tends to accelerate it. This reversal of pressure produces an unsteady rotation and is often responsible for a clatter in the camshaft drive, particularly noticeable at low speeds.

To eliminate the unsteadiness of rotation of the camshaft at low speeds, the camshaft steadying device, which is shown in section herewith, is employed. The end of the camshaft has a male steel cone forged integral with it and another male steel cone is keyed to it. The latter cone rotates with the camshaft, but may slide axially on the shaft. A bronze double female cone is keyed to the camshaft housing, but may slide axially within it. A coil spring pushes the keyed steel cone toward the other steel cone, compressing the female bronze cone between the two rotating steel cones. The friction thus created is enough to give the desired braking effect and to steady the rotation of the camshaft. The camshaft is hollow, and oil under pressure from the oil pump fills the camshaft bore. Oil comes out of the camshaft bore through a hole drilled between the two steel cones and lubricates the surfaces in contact on the steel and bronze cones. As the camshaft rotates, the oil is automatically forced from the small end to the large end of the rotating steel cones by the action of centrifugal force and the increased oil pressure. As the flow increases with the speed of camshaft rotation, more oil is forced out between the cones as the speed of the engine increases, lessening the friction between them. The braking effect, which is only needed at low speed, is consequently reduced as the speed increases.

A good example of the care taken throughout in the design of this engine is furnished by the exhaust valve. In order to keep down the expansion of the stem and head, invar, a nickel alloy steel frequently used in measuring instruments and characterized by a very low coefficient of expansion, is employed. The valve rim, which is exposed to the high temperature exhaust gases, is made of a tungsten alloy and the tip of the valve stem, which is subjected to the continuous hammer blows of the valve follower and consequently requires extreme qualities of hardness, is made of chrome-cobalt steel.

The intake valves, which are not subjected to such high temperature, are made of chrome steel. The valve springs are held on the valve stems by a split collar,

and a cork washer is employed to prevent the oil from flowing down past the valve stem and guides into the cylinders.

### The Cooling System

For simplicity, a thermo-syphon cooling system has been adopted. The capacity of the system being 6½ gal. The radiator is of the tubular type made up of 155 copper cooling tubes with 135 horizontal cooling fins. It is flexibly mounted on two coil springs. For unusually hot regions, the cooling system is supplemented by a condenser placed under the front end of the right splashier. The condenser operates on the principle that the recooling of the radiator creates a sufficient vacuum to draw the condensed water back to the cooling system. This is similar to the systems which have been successfully employed for recondensing anti-freezing solutions in an independent condenser.

The automatic fan release is probably the most unique feature of the Wills Sainte Claire cooling system. A conical bronze bushing is pressed into the fan hub. The fan is pulled backward against the steel cone of the fan shaft by a spring. When in action the fan tends to move ahead on its shaft, and when its speed reaches a certain value the forward pull of the fan, due to the reaction of the air, is stronger than the backward pull of the fan spring. The fan is then pulled off the steel cone and slips on it like a disengaged cone clutch. When the fan speed drops the backward pull of the spring overcomes the forward pull of the fan and the fan reseats itself. To prevent any seizing from the constant slipping of the bronze fan cone on the steel fan shaft cone, both surfaces are lubricated by oil delivered through the hollow fan shaft. As the speed of the fan cannot exceed a certain set limit, the power absorbed for driving the fan is also limited, regardless of how fast the engine may rotate. The speed at which the fan is released is regulated by the spring tension and is generally about 2000 engine r.p.m., which corre-

Sketch of camshaft steadying device to eliminate fluctuation in camshaft speed

sponds to 3000 fan r.p.m. The fan is a three-blade type and is driven off the timing gearset. The fan-and-generator drive gear is of Fabroil and is located at the front of the motor and enclosed within the aluminum crankcase timing gear cover.

### Oiling Circuit

Oil is fed under gear pump pressure to all of the engine bearings. The oil pump is located in the center of the oil sump in the lower crankcase and driven by a vertical shaft off the intermediate shaft through a worm and worm wheel. The pump is attached to a transverse rib of the lower crankcase and completely enclosed by a screen. Both the pump and screen may be removed through the oil drain hole provided in the sump base. The oil is circulated through an oil relief valve of the plunger type located between the oil pump and the crankcase oil header. From this header it branches off

Sectional assembly of clutch and transmission gearset

Eaton axle used in Wills Sainte Claire car. The standard gear ratio is 4.4 to 1

into four circuits for the crankshaft, right camshaft, left camshaft and fan shaft. The crankshaft circuit includes leads to the three main bearings, through the hollow crankshaft to the crankpin and then out through holes drilled in the connecting rod bearing, where it lubricates the surfaces on which the plain rods bear. The oil thrown off the crankpin and the connecting rod bearings lubricates the cylinder walls and piston pins. A detail in connection with the crankshaft oil holes is that instead of being drilled in the customary way, they are drilled off-center and the opening is formed like a scoop which greatly assists in picking up the oil.

The camshaft oil circuit is so arranged that the oil flows from the oil header to the center camshaft bearing through a lead drilled in the upper crankcase half, then through a tube inserted in the cylinder block and through a lead drilled in the camshaft housing. It then flows from the camshaft center bearing to the inside of the camshaft, through a hole drilled radially in the camshaft. Two tubes with expanded ends are pressed into each camshaft, one tube being on each side of the center bearing. Each of these tubes has one radial hole through which oil, coming from the center bearing flows to an annular space between the tube and the camshaft bore. From this space, oil is delivered to the cam face through a hole drilled in the base of each cam, lubricating the cam face, the valve followers and the valve stems. One hole in each tube thus delivers oil to four cams and the oil supply consequently is limited to the required amount.

Oil flows to the front and rear camshaft bearings through the hollow camshaft. The rear end of the camshaft is closed by a plug and the front end is closed by the camshaft front nut. Oil flows out through two holes drilled in the camshaft front nut and lubricates the camshaft drive spiral gear and the camshaft spiral pinion. Excess oil in the camshaft housing is returned to the crankcase through leads inserted in the front and rear ends of the cylinder blocks.

In lubricating the fan shaft the oil flows from the oil header to the fan plain bearing through an oil lead drilled in the upper crankcase half and through a copper tube cast in the timing gear cover.

The clutch is a multiple dry disk, central spring type with six driving and six driven disks. The driving disks carry the clutch lining, which is made of asbestos cord and strands woven into the disks. The particular advantage claimed for this construction is that with the asbestos cord lining, the friction surface is built up of

Chassis wiring conduit assembly. The terminals are numbered to indicate the proper connection. The wire insulations are colored also to distinguish them

a number of cords placed alongside each other. When the clutch is thrown in, the top of the cords come first in contact with the unlined disks and then flattens out as the pressure increases, giving a smooth engagement. It is claimed that with the usual riveted clutch lining, after the car has been driven some time, it is worn down to a smooth surface, and when the clutch is engaged the entire surface comes into contact at once.

The gearset is of selective type with three speeds forward and one reverse. The gearset is housed in an aluminum casing, the front end of which is cone shaped to form the clutch housing. The gears and shafts are made of molybdenum steel. The countershaft is forged integral with the low and reverse speed gears.

There is only one universal in the drive, this being at the front end of the propeller shaft. It is an all metal universal of the yoke type. The universal pin is carried in bushings welded to the housing and is connected to the yoke keyed to the propeller shaft by a two-piece ring. A torque tube of seamless steel tubing encloses the propeller shaft which is connected with the driving pinion through a splined sleeve. The rear axle is semi-floating, with spiral bevel drive. The differential assembly, including the driving gear, the four differential pinions, the differential spider and the differential side gears, is supported in the carrier by two double row ball bearings. Both the pinion and the driven gear are adjustable. There is an inspection plate on the torque tube, giving access to the driving pinion adjustment.

Steel disk wheels are used as standard equipment. The wheels, which are dished outwardly, are of Wills design and made by Budd. The tire equipment is 32 by 4½-in. straight-side cords. The front axle is an Elliot type, the front wheels being supported by double row ball bearings. The steering gear is worm and full wheel and is fully adjustable. The turning radius of the car is 20 ft. 5 in., which is unusually short.

The electrical equipment comprises a starting, lighting and ignition system, which has been specially de-

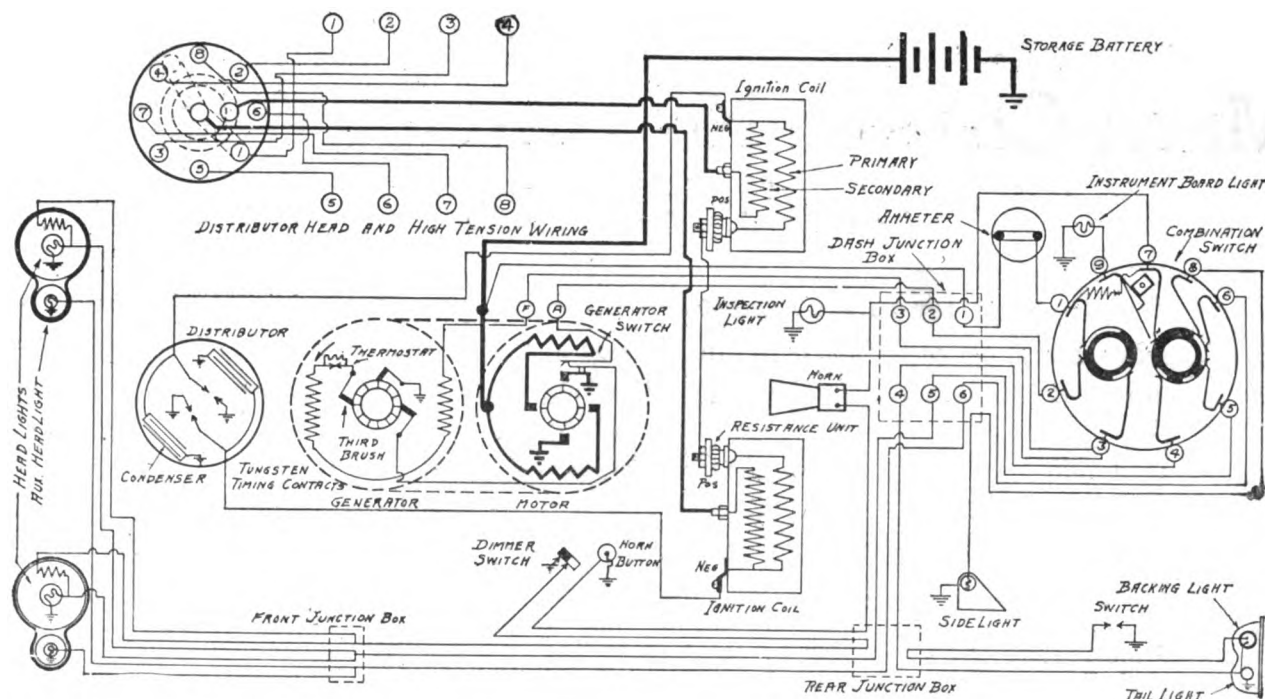

### General Specifications of Wills Sainte Claire

Number of cylinders: 8.  
Angle between the cylinder blocks: 60 deg.  
Bore: 3¼ in.  
Stroke: 4 in.  
Piston displacement: 265 cu. in.  
Compression ratio: 4.1:1.  
Brake horsepower developed:  
30 b. hp. at 1000 r. p. m.  
60 b. hp. at 2000 r. p. m.  
65 b. hp. (maximum) at 2700 r. p. m.  
Specific power: 4 cu. in. per b. hp.  
Rated horsepower for taxation: 33.8 hp.  
Crankshaft bearing length:  
Front 2¼ in.

Weight, touring, fully equipped: 3200 lb.

Wiring diagram of Wills Sainte Claire car

signed for this car by Delco. The distributor and motor generator are driven by the fan shaft. The battery is a 6-volt Willard. All the wires in the car are protected by armored conduits, and the junctions are made in pressed steel junction boxes. Complete wiring is made up in two units, the chassis wiring harness containing all of the wire from the instrument board to the various lights, to the backing light switch and to the steering gear, and the motor wiring harness containing all the wires from the instrument board to the distributor and motor generator and from distributor to plugs.

The lamp equipment is unusual, the headlights being equipped with a magnetic control for tilting the reflector and, in addition to the usual lamp equipment, there is a courtesy or side light located on the left-hand side of the body in line with the windshield post and at about the height of the fender crown. This side light has a 21 cp. bulb and throws a beam directed downward and backward. The purpose of the side light is to illuminate the left side of the road to protect the passengers while entering, leaving or standing alongside the

car at night, and to show clearly to approaching drivers how much clearance they have while passing. In addition to the red tail light, there is a backing light combined with it which is automatically switched on by going into reverse.

The open bodies are built by the Budd company of Philadelphia. They are of pressed steel panel construction, spot welded together. The upholstery is genuine leather with Marshall springs in the cushions. All of the cushions are re-enforced on the bottom by heavy steel wire screening to hold the shape. The upholstery is detachable, the cushions, backs and sides being replaceable quickly and securely in case it is necessary to repair a body panel.

The coupé seats four passengers and is distinguished for its lowness, the distance from the top of the roof to the ground being only 73 in. The instrument board is of harmonious design and carries the Delco switch with lock, Waltham speedometer, Weston ammeter, oil pressure gage, choke button, ventilator button and instrument board light.

## White Company Brings Out a Business Car

**T**HE use of automobiles by salesmen and men whose duties make it necessary for them to travel over sparsely settled territory has increased to an extent that the White company, Cleveland, has developed a special car for this purpose. The new car is a development of the White taxicab, and it has an engine with bore of  $3\frac{3}{4}$  in. and stroke of  $5\frac{1}{8}$  in.

A permanent top gives protection against the weather, and there is ample room for baggage back of the seat.

The price of this business car, including both the chassis and the body, has been set at \$3225. It is understood that the White Co. will not re-enter the passenger car field again and this new model comes in a strictly business class and

A salesman's car

will be merchandised as far as possible in multiple units or fleets.

# Mack Chassis Now Adapted for Use as Rail Cars

Vehicles used for railway work have special axles, wheels and reverse gears, but most other parts of the chassis are identical with those used in standard Mack trucks. Special bodies seat from 25 to 35 passengers.

By Herbert Chase

**S**EVERAL Mack rail cars have been in operation on short line railways for a number of months and are reported to have resulted in such material savings as to assure their early utilization by some of the great railways of the country, chiefly for branch line service. The New York, New Haven & Hartford Railroad has in fact recently ordered three Mack rail cars and has announced that these will be put in service on their branch lines when delivered. These three cars will be constructed largely of components used in the heavy model AC Mack trucks. The Mack rail cars now in the hands of users have all been modified AB chassis, which is the lighter of the two chassis types built by the International Motor Co. Both of the rail cars use, so far as practicable, standard Mack truck chassis units, but both incorporate a number of special features required to adapt the standard chassis to rail service, and both have bodies designed especially for railway use.

The smaller or model AB rail car is designed to carry from 25 to 31 passengers, according to the seat arrangement, grades to be negotiated, etc., but a portion of the body space can be used for a baggage compartment if needed, or a baggage container can be slung under the rear end of chassis frame if desired. When the grades do not exceed 1 per cent a 31 passenger body is recommended. This car makes a speed of 25 to 28 miles per hour on a level track and about 18 miles per hour on a 1 per cent grade. With a 25-passenger body a speed of about 22 miles per hour can be attained on a 1 per cent grade.

The frame of the AB rail car is similar to that used in the AB bus chassis described in AUTOMOTIVE INDUSTRIES for Sept. 15, 1921, and is reinforced with an oak stringer and steel truss rod similar to that used in the bus. The front end of the chassis frame is mounted on a four-wheel leading truck made specially for the purpose by the International Motor Company. The frame of this truck is of considerably lighter material than that used in ordinary railway trucks, but is of a much higher grade of steel. A swinging bolster is employed and the springs are fastened to the body bolster by standard spring pads and spring clips. The body bolster rests in a center bearing in the swinging bolster about which the whole leading truck pivots. The swinging bolster is mounted on swing links which allow side motion and give better riding qualities when rounding curves at high speed.

The wheels of the leading truck are steel forgings 20 in. in diameter with standard Master Car Builders tread and flange. They are mounted on roller bearings and rotate about fixed axles made of high-grade steel. This is in marked contrast to railway practice in which the

wheel is rigidly attached to the axle and the latter rotates in plain bearings. An all-metal pilot is designed in accordance with railway practice and is fastened to the front end of the chassis frame.

The standard Mack double reduction banjo-type axle housing is used. The full floating live axle shafts and double reduction gearing are retained, but the differential is eliminated. A spur gear with large hub is used, the latter being connected by splines direct to the axle shafts. The rear wheels which, of course, do the driving are 38 in. in diameter and have locomotive specification rolled steel tires, with M. C. B. flanges and tread. Tires are pressed on and securely fastened by wedge rings.

A gear ratio of 5.88 to 1 giving a maximum speed of 28 miles per hour on a level track is used in most cases, but other gear ratios are available and can be varied to meet different load, speed and grade conditions.

The standard four-speed transmission is employed, but without the usual reverse gear. A special reverse transmission mounted in a separate housing directly back of the regular transmission is used, but some of the parts used in this are standard transmission parts. The drive through this transmission is direct when the car is running forward. When reverse drive is desired the direct drive-shaft of the special transmission is divided and the power is transmitted to a layshaft and through a reverse gear back to the rear half of the main drive shaft as in a conventional transmission. The special transmission is connected direct to the propeller shaft, which drives direct to the rear axle. By this arrangement it is possible to operate the car at high speed in either forward or reverse direction and on any of the four gears in the

Front view of AC Mack rail car

main transmission. The reverse transmission is operated by a separate lever. When this is in reverse position the regular transmission is operated in the conventional manner.

The standard hand brake operating on the propeller shaft and foot brake operating on the rear wheel drums are employed. In addition the standard steering gear is used to operate four shoes one of which bears on each of the four wheels of the leading truck. These brakes are used in service as much as possible in order that the foot and hand brakes may be held in reserve for emergency purposes.

Sanders for use when traveling in either forward or reverse direction are provided. They are operated by a lever from the driver's seat.

Bodies are of substantial wood construction and are made by experienced railroad-car builders. The 31-passenger body is 21 ft. 6 in. long inside. With this length of body the wheelbase is 198 in. The 27-passenger body is 19 ft. long inside and is used on a 180-in. wheelbase chassis.

The larger or AC type rail car is designed to carry 36 passengers and about 1000 lb. of baggage and to have a maximum speed of 35 m.p.h. on level track. It has the following special features:

The frame has 5/16 in. chrome-nickel heat-treated side members 31 ft. 10 in. long. To the outside of these are riveted substantial steel re-enforcement members. In order to lower the frame the springs are hung under the rear axle and are attached to the frame by rubber shock-insulators in place of shackles. These insulators are used at both ends of both springs. They tend to improve the riding qualities and prevent the shock of passing over rail joints from reaching the frame of

the vehicle. All springs are of the half-elliptic type.

The front end of the chassis is carried on a four-wheel leading truck of the same size and design as that used on the smaller AB rail car.

The rear axle is of special design since the large gear reduction obtained by the chain drive employed in the AC Mack truck is not required for railway work. The axle housing is of cast steel, and a single reduction bevel gear drive is employed. A simple flange to which the ring gear is bolted replaces the usual differential, which is not required, and drives the two live full-floating axles through splined connections. The wheels are of cast steel 40 in. in diameter and have rolled steel locomotive tires shrunk on. They are mounted on the axles with large Timken bearings with considerable space between the inner and outer bearings of each set. Timken bearings are also used each side of the ring gear and on the bevel pinion shaft. The standard 56½-in. gage is employed. Special tubular radius rods 5 ft. long are used.

The standard four-speed AC transmission is used but without the usual reverse gear. However, the rear end is modified to take a propeller shaft connection instead of the jackshafts and bevel gears used on the chain-drive truck. A reverse transmission identical with that used in the AB rail car is employed, but in this case it is mounted between the engine and the standard transmission. As in the smaller rail car it enables high speed operation in either direction and is controlled by a separate operating lever.

No conventional automobile type brakes are used on this car. In place of these there are brake shoes acting on the periphery of all six wheels. These are arranged to be operated normally by air pressure as in ordinary

Plan and side views of Mack AC rail car with baggage compartment and seats for 36 passengers

railway work, but in an emergency can be operated by a wind-up hand mechanism. It has not yet been decided what means for compressing air will be employed, but a special air compressor driven off either the engine or the transmission, or accumulators using compressed gases from the engine cylinders may be employed.\*\*

A spark and throttle control column is used in place of the steering gear column which is not required.

Sanders operated by a lever from the driver's seat and similar to those used on the smaller car are employed. The exhaust gases are carried to the extreme rear end of the chassis frame. The pipe used is so long that no muffler is required.

The wheelbase measured from the center of the leading truck to the center of rear wheels is 22 ft., which is within the fixed wheelbase allowed on locomotives. This permits of the car being operated at moderate speeds on a curve of 40 ft. radius. The total track length of the car is 24 ft., hence a turntable of this diameter can be used to turn the car around.

It will be noted from the accompanying drawing that the body is 9 ft. wide and 27 ft. 3 in. long, inside measurements. It will seat 36 persons and has in addition, at the rear, a baggage room measuring 6 x 9 ft.

Both sizes of rail car have provisions for exhaust heating. The exhaust can be bi-passed through guarded pipes extending along the inner body walls of the body.

Electric starters are provided for the engine in both

sizes of car and both are fitted with miniature 12-volt train lighting systems driven from the engine and consisting of dynamo, a dynamo-lamp regulator, storage batteries and 10 dome lights.

The chassis weight is 13,675 lb. The total weight with body, 36 passengers and 900 lb. of baggage is estimated at about 26,000 lb.

The AB rail car is fitted with a standard 4-cylinder, 4 by 5-in. engine, governed to run at a maximum speed of 1450 r.p.m. The engine in the AC car is the standard 4-cylinder 5 by 6-in. type governed to a maximum speed of 1250 r.p.m. Both engines are fitted with high-tension magnetos with impulse starters.

The cost of operating rail cars depends largely upon the price of labor and supplies, the size of the crew required and other local conditions. Either car is suited for one-man operation if this is desired and permitted under Federal and State laws and local ordinances. The following items serve to give an idea as to the operating cost over a 24-day period in the case of one of the AB rail cars operating over a short line railway. (Figures cover the car only. They do not include fixed or maintenance charges on the road bed.)\*

Fixed charges, including amortization, interest and insurance .....	\$88.55*
Maintenance, including roundhouse charges, \$20; Washing and polishing, \$5; chassis repairs, \$10;* body repairs, \$1;* repainting, \$5;* chassis overhaul, \$7;* lubrication, inspection and adjustment, \$3.50*.....	51.50
Running charges, gas (11 m.p.g.) at 25c. gal., \$50; oil (200 m.p.g.) at 60c. gal., \$6.60; running supplies, \$5;* operator's wages, \$92.40.	154.00
<b>Total operating cost (24 days).....</b>	<b>294.05</b>
<b>Cost per mile (2200 miles total).....</b>	<b>.1336</b>

\*\*The AC rail car is not yet completely developed. An experimental car has been under test for some time, but several changes, most of which have been covered in this description, have been made partly as a result of experience gained with the experimental car and partly to meet the views of the railway which is purchasing the three cars now being built to their order.

\*Some of the items here given represent actual costs in a particular case and others are estimated and pro-rated for the twenty-four day period, basis of estimated yearly charge, but they are said to serve as a reasonable basis for comparison.

Steam train operation is said to cost in the neighborhood of \$1.50 per mile, but this cost also varies greatly with local conditions. However, the difference in operating costs is very much in favor of the rail car.

On the other hand the rail car is not expected to fill the field of the steam passenger train when this can be run to capacity, carrying, for example, 70 or more passengers. Its field appears to be in localities where traffic is relatively light and is spread over the day without

pronounced peaks, exceeding the car capacity, especially where service must be provided without respect to the volume of traffic. Under these circumstances the saving in operation as compared to steam is considerable.

The manufacturers of the Mack rail car do not recommend the use of trailers unless much lower speeds on grades are not objectionable and it is permissible to reduce the seating capacity of the leading car, but trailers have been used with satisfaction in some instances.

## New Line of Internal Gear Truck Axles

**D**URING the past year the Russel Motor Axle Co. took advantage of the lull in business to develop a new line of motor truck axles of the internal gear type. This development work has now been completed and the axles have been placed in production. All of the models possess the same characteristics and embody a good many improvements over previous designs.

The new models will be made for 1, 1½, 2 and 2¾ ton trucks. With the exception of the 1½-ton they will

replace previous designs, the Models P, S and U. The 1½-ton model is an entirely new design, gotten out to meet a demand for that size which has been felt recently. A drawing of the Model 6000 axle is reproduced herewith, and, except as regards dimensions, will serve to illustrate all of the different sizes. The improvements incorporated in this new line of axles may be briefly enumerated as follows:

Spiral bevel driving gears are used for the first reduction set on all models, which insure a degree of quietness not obtainable with straight tooth bevel gears. On Models 3000, 4500 and 6000 the pinion shaft is machined with ten splines for the universal joint flange. Model 8500 has a taper for the flange. An improved four-pinion type of differential gear is used on all models, this differential incorporating hardened and ground thrust washers.

The jackshaft pinions are mounted upon the jackshaft in such a manner as to permit removal without disturbing the

jackshaft. An enclosure for the jackshaft pinion bearing is provided. An enclosure for the internal gear and jackshaft pinion is fitted to protect these parts from dirt and also retain the lubricant.

The operating mechanism for the external brake is greatly improved and an adjustment for the brake lever is provided. Provision is made for adjusting the wheel bearings.

# Automatic Declutcher Introduced at Paris Show

Gear shifting accomplished by taking the foot off the accelerator pedal and waiting until engine slows down to a point where it is sure to be uncoupled by the new device. The gear lever is then shifted without disengaging the friction clutch. Makers claim fuel saving as an advantage.

A NOVELTY introduced at the recent Paris show is the free-wheel or automatic declutcher known as the "Autodebrayage T. L.," which is incorporated in the line between the friction clutch and the transmission. The device is fitted to the latest model of Chenard-Walcker car. Its effect is that whenever the car tends to run ahead of the engine, the latter is automatically disengaged, but as soon as the car has slowed down to a speed corresponding to the throttle setting the connection between engine and drive is automatically re-established.

## Leads to Fuel Saving

The chief advantage claimed for the automatic declutcher is that it helps to save fuel. In city driving, car control is almost entirely by the throttle. When the car speed has to be slackened, the throttle is closed as far as possible while still keeping the engine running, and the engine may then be turned by the car at, say, 1000 r.p.m., while the throttle is set for, say, only 400 r.p.m. Although the throttle is nearly closed, the suction on the gasoline nozzle will be fairly strong and much gasoline will be wasted.

The device is claimed to have a favorable influence also on the manipulation of the change gear lever. In changing from a lower to a higher gear, the foot is taken off the accelerator pedal and the driver waits a moment until the speed of the engine has come down to a point where the engine is sure to be uncoupled by the auto-declutcher; he then merely shifts the gear lever into the slot corresponding to the speed which he wishes to engage without disengaging the friction clutch. In the case of a change from a higher to a lower gear it is only necessary to shift the gear lever from one slot to the other as fast as possible, without disengaging the clutch. It is sometimes an advantage to slightly release the accelerator pedal before shifting gears, so as to insure that the "autodebrayage" has become disconnected in advance.

Referring to Fig. 1, consider a female cone M secured to the driving shaft, which is adapted to engage a male cone C, this latter forming a nut screwing over a slow-pitch thread cut on the driven shaft (in this case the primary shaft of the transmission). Suppose that the whole assembly is turning in the direction indicated by the arrows and that the screw is a right-handed one,

as shown; then, if the driven shaft really opposes considerable resistance to the motion, the combination of the male and female cones forms a solid block which tends to move in the direction from y to x. But both the driving and the driven shaft are held against endwise motion; the only piece which can move in an axial direction is the male cone C, and the latter is forced into the female cone with a force proportional to the resistance to motion of the driven shaft.

Now suppose the rôle of the two shafts reversed, that the driver becomes the driven shaft and vice versa. This occurs when the car is under way and the accelerator pedal is then released. The shaft R then tends to run ahead of the flywheel M, and, contrary to what occurred in the previous case, the flywheel and cone assembly then tend to move in the direction from x to y. The

flywheel being fixed against endwise motion, only the cone is displaced toward y, and uncoupling of the engine takes place. The flywheel is then free with respect to the cone and of the driven shaft which is integral with the latter, this state of affairs continuing as long as R turns faster than M in the direction of the arrows.

With such a device it would ordinarily be impossible to make use of the engine for braking purposes in descending long hills. This objection is met by the argument that the four-wheel braking system is coming into use, and with brakes on all four wheels there is no danger of the friction bands being injured by overheating on long downgrades. Attention is also called to the great waste of fuel due to descending hills on the engine. However, the inventors of the device have evolved an arrangement by which the automatic uncoupler comes into action only on the two higher gear combinations, so that it is still possible to use the engine as a brake on the low gear.

## Operative on Higher Gears Only

When it is desired that the "auto-declutcher" shall operate only on the high and intermediate speeds it is located inside the intermediate speed gear on the sliding or splined shaft instead of between the clutch and the primary shaft of the transmission. In that case, when the low-speed gear is in use, the power does not pass through the intermediate-speed gear and the auto-declutcher is then non-effective.

Fig. 1—(Left)—Diagram of automatic declutcher. Fig. 2—(Center)—Automatic declutcher located inside intermediate speed sliding gear. Fig. 3—(Right)—Out-side view of threaded sleeve

# Standardizing Differential Gears

Committee of American Gear Manufacturers' Association working to bring about similarity in design to permit interchanging of differentials of different makes. Committee also studying methods of gear improvement.

**I**N the past the suggestion that differential gears be standardized has repeatedly been made in these columns, and it seems that now something is going to be done along this line, as the American Gear Manufacturers' Association Standards Committee has appointed a sub-committee on differential gears. The bevel type of differential gear, which has now been used in automobile construction without important change for more than twenty years, and which at the present time is used on probably more than 90 per cent of all the cars turned out, lends itself well to the standardization of a few of its important dimensions, so that differentials of the same capacity rating but of different make are interchangeable on the same car. There are now a number of firms specializing in the manufacture of differentials, and if the dimensions referred to were standardized and the standards were given wide publicity, designers of cars, trucks and tractors would not bother about designing special differentials but would adopt a design conforming to the accepted standard, which not only would save the differential manufacturers much unnecessary outlay for patterns, dies and fixtures, but would redound to the advantage of the whole industry.

At the recent meeting of the A. G. M. A. a preliminary report of the new subcommittee on differentials was received, which contained a program of the proposed work of the committee, together with comments on the different topics, and furnished an interesting outline of the problems confronting the manufacturers of differentials. The report is due to S. O. White of the Warner Gear Co.

It is the intention of the committee to standardize the internal parts of differential gears so that these parts from different factories are interchangeable. As far as the work of the committee is concerned, the driving bevel gear is included within the scope of its activities. The form of this gear is, of course, largely determined by the diameter and lateral location of the flange on the differential housing to which it is fastened. Attention is called in the report to the importance of choosing the proper section for these gears, as some sections do not distort as much as others under heat-treatment.

The subject of close-fitting inside gears and pinions demands investigation, as it is bound up with the backlash and noise of the axle. The buying public has become very meticulous with regard to noises in the transmission, and any knocking or clicking noises, even at the lowest car speeds on direct drive, are strongly objected to. This means that every bit of play or lost motion from the motor clear back to the rear wheels must be done away with if at all possible. The driving bevels, which are constantly in operation, must of necessity have a certain amount of backlash for smooth running, but it has been found that the inside gears of the differential, which operate only occasionally, can be fitted up tight.

It is the purpose of this committee to gather from all members manufacturing differential gears data of unsuccessful or troublesome designs for guidance in future work. Much of the trouble with differential gears at pres-

ent is due to improper mountings, and it is the purpose of the committee to recommend properly designed mountings adequate for the load to be carried. Trouble has been especially prevalent on axles with spiral bevel gear drive, as many designers have attempted to use substantially the same mountings as they formerly used with straight bevel gears. With the spiral bevel gears the end thrust loads are greatly increased, and unless allowance is made for this in the mounting the mesh and alignment of the gear and pinion are apt to be disturbed. As a general thing, lightness is desirable in a rear axle for a number of reasons, but it is very easy to overshoot the mark in this direction. This will inevitably lead to dissatisfaction of the owner, and it is far better to err on the side of too much weight.

Excessive end thrust loads, or inadequate provision for them, being one of the causes of trouble with differential gears, the factors affecting end thrust are to be investigated. As regards thrust on the pinion shaft, this is in part due to the sliding joint on the propeller shaft, and is affected also by the method of springing or hanging the axle. Naturally, the nearer to the straight line drive the car approaches, the less will be the thrust due to the slip joint. Bearing loads depend to a certain extent on the adjustment of the gears, and easily accessible adjusting means should be provided on each axle. It has been proved that a bevel and pinion which will run quietly when transmitting the load for which they were designed, will operate noisily when crowded on the end of the pinion shaft. In traveling over uneven roads it is impossible to completely prevent this crowding action, but the bearings and mounting should be sufficiently strong to take care of it, and the outside connections should be so arranged as to minimize this action.

Occasionally, in conjunction with the Hotchkiss drive, fabric universal joints are used without any slip joint in the line, and unless this design is very carefully laid out so that the drive is very nearly in a straight line when under normal load, there is apt to be excessive end thrust on the pinion shaft.

Improper lubricants are often used in rear axles. Some owners seem to think that any old grease will serve the purpose, and generally the more noisy the axle the heavier the grease that is put in. The best results from the standpoint of lubrication are obtained with a lubricant that is comparatively fluid, but unfortunately some axles are so designed that a lubricant of this kind will run out onto the brake drums. Axles should be so designed that a fluid lubricant will not run out. As regards the lubrication of the parts of the differential itself, it is believed that a good purpose would be served by formulating standard practices as to oil holes, oil grooves and channels.

In the inspection of differential gears one of the most difficult things is to make an accurate determination of the noise of operation of the gears, that is, the driving gears located on the differential. It is the hope of the committee that a sound recording device will be worked out that will be simple enough for ordinary shop use.

# A Remedy for Spring Breakage

Majority of spring failures are clean breaks of the top leaf. The cause of this is probably because this part takes the driving and braking forces in addition to carrying the load. A thin top leaf has proven more efficient than those made the same thickness as the other leaves.

By Frederick Franz

**T**HERE are only a few structural combinations in engineering which can be made stronger by decreasing their size, but the top or main leaf of a Hotchkiss drive spring, puts these springs in this category.

The failure of springs in service is due to a break in the eye, in the top leaf, in the bottom leaf or in an intermediate leaf. Men who made repairs on army trucks used in the war have declared they have had the upper leaf of the spring doubled over on itself without breaking. But the overwhelming majority of Hotchkiss spring failures which came under my observation were clean breaks of the upper leaf just outside of the spring cap and on the driving half of the spring, that is, the half opposite the shackle end. Upon inquiry the manager of one of New York's largest spring repair shops told me that almost all Hotchkiss drive springs brought to him for repairs had the top leaf broken.

Why does the top leaf break? Because it takes the driving and braking forces in addition to carrying the load.

Fig. 1

Fig. 2

Fig. 3

Fig. 1—Stress in spring under simple vertical load. Fig. 2—The thin top leaf in its relation to the other leaves. Fig. 3—An enlarged view of the thin top leaf

How natural, then, to say, make it a gage number thicker to resist the extra stress. But since, under simple vertical loading, all leaves have the same curvature (all being in contact throughout their length), the thick top leaf already has a greater maximum fiber stress than the thin remaining leaves, so that when the compression due to starting or the tension due to braking is thrown upon it, the maximum fiber stress is further increased, resulting in a rupture. We will consider this in detail later.

Spring makers did not recognize this phenomenon, but knew that the breakage was due to the driving and braking forces, so they hit upon the method of "cambering" the leaves which put initial stress in the spring, in such a way as to favor the top leaf, which was kept thick. Cambering consists of forging the individual leaves so that the upper leaves are not curved as much as the lower leaves, which has the effect, when the leaves are clamped together by means of the clips, of putting "negative" stress in the upper leaves but "positive" stress in the lower leaves with no stress in a leaf somewhere near the center. The amount of camber is determined by judgment. If too great, the bottom leaf breaks; if too small the top leaf breaks. The initial stress lowers its capacity for carrying a load. The scheme is a combination of so many variable and illogical factors that any different results cannot be expected.

## The Remedy

The remedy is to make the top leaf thinner than the rest and omit the camber, coming back to first principles. Under simple vertical load, then, the maximum fiber stress in the upper leaf is less than that in the other leaves, leaving a margin for the additional stresses which are applied when starting and stopping the vehicle.

The practice of a thick upper leaf is so universally accepted that a prominent Chicago spring maker almost refused to supply me with springs for an electric truck I designed having the top leaf thinner than the remaining leaves calling my attention to the "unusual procedure" and stating he "felt sure that it is advisable to make the main leaf somewhat heavier stock than the other leaves." The first set of springs designed on the new principle has now been in operation almost a year under heavy service and shows no signs of breaking. Springs of the old design with thick upper leaves broke in exactly the same service about once every two months.

## Qualitative Analysis

The stresses in a spring under simple vertical load are shown in Fig. 1, the arrows showing the direction of the bending moment acting on the spring. The sloping line shows the variation of stress in each leaf, from the maximum stress in tension  $T$ , to no stress at the neutral axis  $NA$ , and to the maximum stress in compression  $C$ . In a properly graduated spring, with all leaves of equal thick-

ness, the maximum stresses are equal in all leaves and at all points in the same leaf as  $T$  and  $C$ . The slope of the line showing the variation of stress depends upon the amount that the spring is deflected, but not upon the thickness of the leaf. See any text-book on Strength of Materials. Therefore, a thin leaf, on top of these leaves, as  $A$  in Fig. 2, has a maximum fiber stress of only  $T_1$  as compared with  $T$  for the remaining leaves (this diagram is exaggerated to show the difference—in practice the top leaf is only a few gage numbers thinner).

Fig. 3 shows the enlarged view of leaf  $A$ . If the leaf is under bending stress as shown, and a tensile pull is placed on the leaf in addition, the maximum fiber tensile stress will increase from  $T_1$  to  $T_2$ , the stress at the previous neutral axis will increase from zero to  $M$  and the maximum fiber compressive stress will decrease from  $C_1$  to  $C_2$ . For the correct spring  $T_2$  should not be greater than  $T$ , Fig. 2.  $M$  is equal to  $T_2 - T_1$ , and is the margin that must be allowed for the driving stresses.

#### How to Calculate the Thickness of the Upper Leaf

The thickness and number of leaves should first be determined on a basis of all leaves having the same thickness, under maximum load on vehicle and maximum torque on wheels. The forward thrust for propelling and the retarding force due to braking should then be determined and divided by the sectional area of one leaf to obtain the unit stress, assuming uniform distribution of stress. This is the margin  $M$ , Fig. 3, which, if subtracted from the maximum safe stress  $T_2$ , will give us the maximum stress  $T_1$  to which the upper leaf may be subjected under simple

vertical load. Knowing the rate at which the fiber stress increases from zero at the neutral axis to  $T$  at the surface of the leaf a thickness can be chosen on the sloped line at which the stress will be  $T_1$ . This is the thickness of the upper leaf.

For example, if the thickness of the leaves, all being uniform, calculates to .3125 in., No. 0 gage, and the width to 2 in. with a maximum allowable fiber stress of 75,000 lb. per sq. in., and the maximum thrust on each spring is 2000 lb., the sectional area of the leaf, .3125 in. x 2 in., or .625 sq. in., divided into the 2000 lb. gives 3200 lb. per sq. in., the margin for thrust. The stress in the upper leaf due to vertical load should then be 75,000 — 3200 or 72,800 lb. per sq. in. The thickness of it would be  $(72,800 \div 75,000) \times .3125 = .3033$ . The nearest thinner standard size is No. 1 gage, .281 in. thick.

In designing Hotchkiss springs on this new principle I have made the first leaf under the top leaf the same length as the top leaf, to avoid overhang of the thinner top leaf at its ends. The advantages of springs which are flat under normal loads are now fully recognized, and this type is being incorporated in new designs, but since it has a reverse bend under maximum load, care must be exercised not to make the top leaf too thin in order that crippling or buckling of the top leaf under compression thrust may be avoided.

This principle is given to the automotive industry to help eliminate the great annual waste due to spring breakages, not only in new designs, but in repairs also, and to suggest a new line of thought and action for still further improvements.

## A Uniflow Manifold

**A**N interesting form of intake manifold is under development by the Brookins Mfg. Co., Inc. This manifold is designated as a uniflow type because the gases are continually circulating in one direction. This circulation is induced by the velocity head of the intake gas, the advantage claimed being the elimination of surge.

The manifold is intended to eliminate pulsation and condensation within the intake passages and to help prevent crankcase dilution without the application of excess heat. It is claimed that this type of manifold, which keeps the intake gases in continual circulation, eliminates irregular running at various throttle openings when accelerating.

The sketch herewith, Fig. 1, is a diagrammatic representation of the intake manifold. As will be noted, the gases are led past the cylinder ports and around back into the manifold again through a venturi formed in the outlet end of the intake passage. This outlet end

Experimental installation of uniflow manifold on Marmon car

Diagram of principle of Uniflow manifold being developed by the Brookins Mfg. Co.

is led directly into the center of the stream at the intake end of the inlet.

This manifold has been tried out extensively on racing cars on the Pacific Coast and is also being used in experimental work at the present time at McCook field. In a test made on the manifold by the General Motors Laboratory, a 1-in. uniflow manifold was used in comparison with a 1 3/16-in. conventional type on a Northway light-six engine. No heat was applied to either manifolds. The material increase in economy obtained was due, it is claimed, to better distribution.

# Automobile's Influence on Machine Tool Industry

Old shop methods discarded to make way for machinery of the most modern type that is demanded in the up-to-date automobile factory. The demand for speed in production has brought out numerous machines equipped with mechanical speed-change heads and multiple cutting tools

By F. K. Hendrickson\*

**D**URING the years 1910 to 1913 the automobile industry began to exert a great deal of pressure on machine-tool manufacture and design, and about this time several concerns found it necessary to make extensive and very expensive changes in their systems of production to meet the rapidly increasing demand for cars. To arrive at the best conclusions and in order to secure the most modern installations, they invited many of the best engineers and machine-tool manufacturers in the country into conference with them. Each individual piece was considered separately and at times in the presence of two or more representatives from different firms, with the result that highly specialized machines were rapidly developed.

A brief study of the developments in machine-tool building attributable to the demands of the automotive industry, therefore, seems desirable at this time, taking up in their order the following elements which go to make a successful machine: (1) Materials and their proper distribution; (2) precision and specialization; (3) power; (4) manipulation; (5) speed; (6) lubrication; (7) safety devices.

## Materials

Every mechanic is fully aware of the extremely rigid construction which has been demanded, due to the ever-increasing strains to which machines are subjected. In addition to the extra weight thus entailed, materials of high tensile and torsional capacity have been substituted. A few examples will suffice to indicate the trend.

Lathe spindles originally 30- to 40-point carbon steel are now made of 15- to 20-point steel, being carbonized and hardened to produce glass-hard surfaces. The diameters also have been greatly increased.

Lathe centers formerly quite small, unhardened and of low-grade tool steel are considerably increased in size and hardened at the point on both head and tail stocks.

High-speed cutting tools generally supported in special rigid holders are replacing almost entirely carbon-steel lathe and planer tools, twist drills, reamers, milling cutters, taps and dies.

Babbitted journals or bearings are rapidly being replaced by the best-quality bronze metals, and the tendency is toward the application of ball bearings. Certain types of machines have already been forced to incorporate them on their main spindles and with success, which indicates that the same conditions will ultimately obtain in other machines.

Cast-iron gears for speed and feed changes have been discarded in favor of the hardened steel gears, except in a few machines where the speed changes are accomplished by the engagement of friction clutches, thereby permitting the gears themselves to remain constantly

in mesh their full depth and width of tooth, and eliminating the shock that otherwise results.

Clash gears, either of the sliding or tumbler type, have proved absolute failures when made of cast iron or soft steel, but are satisfactory when made of the proper steel and subjected to suitable heat treatment.

In addition to producing gears of wear-resisting qualities, it has also been necessary to develop their efficiency and to produce much quieter running. To accomplish these conditions, several machines are to-day equipped with helical or herringbone gears to produce smooth action and silent running under high speed and strain. New forms of spur gears are also being developed which are claimed to successfully meet the requirements.

## Precision and Specialization

Grinding machines have been brought to a high state of perfection and produce a truer and finer quality of work on all revolving and sliding parts much more rapidly than ever before. Closer limits and tolerances have been demanded, with the result that the one-time all-around mechanic has been replaced by the present specialized expert in order to obtain the highest grade of precision in quantity.

## Power

Along with the added strength and rigidity of the machines must necessarily be considered their power. The automotive industry has accomplished much in the direction of insisting that the drive shall be either of the geared or silent-chain type to prevent slippage, usually prevalent when machines are belt-driven. The

\*A paper read before the American Society of Mechanical Engineers.

individual motor installation has also come into common use, and at the same time the horsepower of the motor has been increased sufficiently to care for the extreme loads.

For example, a few years ago a 14-in. geared-head lathe was equipped with a  $\frac{3}{4}$ -hp. motor, while to-day the machine must be provided with a motor of 2 hp. at least and preferably 3 hp. This proportion may not be general for all classes of machines, but is a fair criterion of the present condition.

### Manipulation

One of the very essential features demanded in present-day machines by the automotive industry is easy manipulation and the convenient location of the operating levers, handwheels and cranks. Speed- and feed-changing mechanisms must be located within easy reach of the operator and must not cause him any undue exertion or unnecessary delay.

Where there is a sufficient quantity of pieces and the parts lend themselves to magazine or hopper feed, these must be included in order to assist in the handling of work. If the parts are heavy or bulky, mechanical or electrical handling devices must be provided in order to secure high production.

### Speed

Several years ago speed bosses were practically unknown, but with the advent of the automobile era has come this type of functional foreman and with him a demand for readily obtaining in a given machine the proper speed and feed for the work. To meet this ever-increasing demand machine-tool manufacturers have in general incorporated mechanical speed-change heads and quick-change gear boxes for feed variations in their machines. Motors of the variable-speed type are used when mechanical changes are not available.

It is interesting, however, to note certain specific conditions which, although contrary to the general demands, have worked out in the most gratifying manner. During 1912 and 1913, in a well-established automobile plant in Detroit, the production of transmission parts was receiving the most careful consideration as to the best method to adopt to materially increase their already heavy production. It was finally decided to adopt a single-purpose lathe having one speed and one feed, properly calculated to obtain a maximum production for each individual piece.

The Reed-Prentice Co. of Worcester, Mass., placed the first of these single-process automatic lathes into actual operation, and, much to the satisfaction of all concerned, the production was increased from 25 to 50 per cent. Additional machines of the same type were then installed in larger batteries and in each case the production was increased proportionately.

The theory of establishing a single speed and single feed was to eliminate the judgment of the operator and to predetermine the day's output. If this was not obtained the cause was readily detected and almost as readily remedied.

In the machine referred to certain features were introduced which permitted the increase in production. The spindles were much shorter than in a standard lathe, while the bearings and journals themselves were longer than ordinary and much larger in diameter, with the journal bearings of the spindle carbonized, producing glass-hard surfaces.

The driving gears were extremely wide and of the herringbone type to permit smooth action under high speed without any perceptible vibration. The rack and pinion were hardened, as it was discovered that under

actual production conditions the severe strains to which these parts were submitted finally bent the teeth very perceptibly and caused them to wear out rapidly.

The hand-wheel type of tail-stock was replaced by a cam attachment for quick approach and withdrawal of the spindle, permitting a travel of from 1 to 3 in., according to the requirements of the work.

In order to obtain the squaring of the shoulders during the actual process of turning, a back-arm attachment was incorporated, actuated by the travel of the carriage, so that when the longitudinal turning was completed the shoulders were simultaneously finished, thus producing the squaring operation at practically no additional cost. This, however, was not an absolutely new feature, having been previously employed.

To further assist in speeding up production multiple tools are used, and when the pieces are in sufficient quantity and adapt themselves to multiple operations, single-purpose machines of special design are brought out.

A very simple but most efficient method for securing quantity production is to use several arbors, some for loading while the others are working. Also, when applicable, a punch press is used for an arbor press, simultaneously loading one arbor and unloading another, this, of course, being used only where a battery of machines are operating on the same kind of work and call for a number of arbors of the same size, and where a conveyor is used to carry the work from the press to the lathes and return.

Air cylinders and quick-action, mechanically operated chucking or gripping devices are used wherever possible. Magnetic chucks and plates are also in extensive operation.

### Lubrication

The seriousness of having 25 to 100 separate oil holes spread out promiscuously all over a machine is beginning to be realized. The neglect of any one oil hole invariably causes a hold-up of production and may mean the entire dismantling of the machine. Therefore, it becomes obvious that to control the lubrication from one point is decidedly advantageous. This is accomplished either by supplying a reservoir having gravity feed, by gear pumps delivering lubrication to the various bearings, by the use of the splash system or by use of force-feed oilers. In fact, there are several methods, all of which are worthy of consideration.

### Safety Devices

The working forces of automobile factories comprise many who never saw a machine tool prior to their employment, and it is this class of help that has made it necessary to safeguard every moving part of a machine to prevent them from getting injured. Years ago gears were left exposed and shafts allowed to run in the open, but the machines of to-day must include guards over every part that is in the least dangerous. Projecting shafts must be guarded, and where it is impossible to supply guards as part of the machine, rails or nettings must be secured around the machine to prevent any possibility of injury.

A SWISS correspondent states that the advanced Swiss import tariff cannot be continued, as its effect is already causing consternation among Swiss traders, who are in fear of retaliatory measures from which the country would stand to lose far more than any hoped for gain. Automobiles would be very badly hit by the new tariff. A revised schedule is expected to be issued very soon. The new rates only came into operation in July last.

# Present Status of the Farm as Motor Truck Market

United States Department of Agriculture survey shows that 95 per cent of eastern farmers, on various types of farms, consider their truck investments profitable. The time saving element and ability to get to better markets are greatest advantages, while poor roads present a drawback.

**T**HE farm as a market for motor trucks has long been recognized. Many farmers, almost as soon as other industries adopted motor transportation for commercial work, purchased trucks, although it has only been in recent years that their use has been anything like general. There is still a large market among the farmers, especially in districts where road improvement is well developed. It is true that a great many men in the agricultural districts have refrained from purchasing trucks because the highways in their section were such as to prohibit motor traffic during a considerable period of each year. On the other hand, some farmers, unwilling to take the initiative, have waited to see whether or not the truck would prove valuable for farm purposes, even though they were blessed with good roads.

The United States Department of Agriculture recently conducted a survey among farmers in the New England and Middle Atlantic states to obtain information as to whether or not the use of trucks on farms in those sections is satisfactory. While the purpose of the survey was to enable the farmer to benefit by the experiences of others, the data obtained will prove valuable to the manufacturer in marketing his product in agricultural communities. At the outset it is interesting to note that 95 per cent of the farmers replying said their trucks bade fair to be profitable investments. The greatest disadvantage of the truck on the farm was given as poor roads by 59 per cent of the farmers. The size of trucks most prevalent in the rural sections is also of major importance to the manufacturer. Over half of the total number accounted for in the survey are of the one-ton size, while only about 2 per cent are rated at more than two tons. The sizes range from one-half ton to five tons.

## Types of Farms

There were 753 answers received to the questionnaire, divided by states as follows: New York, 241; Pennsylvania, 235; New Jersey, 92; Massachusetts, 63; Maryland, 40, and lesser numbers in the states of Maine, New Hampshire, Vermont, Rhode Island, Connecticut and Delaware.

The following table shows the division of these trucks among the various kinds of farms and the average distances of each kind from the market:

Kind of Farm	Average Size	Number of Trucks	Distance from Market
Truck .....	64 acres	149	12 miles
Dairy .....	234 acres	129	6 miles
Fruit .....	111 acres	113	11 miles
Crop .....	237 acres	48	8 miles
General .....	210 acres	314	11 miles

Crop farms in the above table indicate that only general crops are raised, and there is no dairying or live stock. General farms are those on which there is no predominant enterprise, but on which all have a part. The fact that there are more trucks used on this latter class does not indicate that the percentage of such farmers who own motor trucks is larger than that of men who follow special types of farming, but that in this region there are more general farms than any other type. It will be seen that practically every phase of the farming industry is covered in this questionnaire, and the fact that most of the farmers considered their trucks a profitable investment suggests the conclusion that motor trucks are practical on nearly all farms in territories supporting passable highways for a reasonable period in each year. Of the few farmers who found trucks unprofitable most of them were those who said their machines were unreliable, out of order when needed, or expensive to keep in repair. A few said they did not have enough work to justify investment in such an expensive piece of equipment.

## Advantages Set Forth

Just why the farmer finds his truck valuable was shown in the answers to the question, "What have you found to be the principal advantage of a truck for farm work?" The answers were divided as follows:

Saving time, 92 per cent.  
 Saving horses, 3 per cent.  
 Better markets, 2 per cent.  
 Convenience, 2 per cent.  
 Reduction of expense, 1 per cent.

The time-saving element, it will be seen, is the most important one to the farmers, but it should be borne in mind that this element combines practically all of the other four reasons, or at least has a direct bearing upon them. Certainly, better markets should play an important part in the farmers' economic scheme of things, and it does. The motor truck has played an important part in securing better markets, for while the replies do not place this item at the top of the list, nearly one-fourth of the total are now selling at better markets than they did before. The farmer who lives four miles from a poor market and 15 miles from a better one can ill afford to spend the time driving horses to the one 15 miles away for the sake of a comparatively small difference in the price he receives for his goods. But with the motor truck at his disposal the difference in time consumed is small, and the better market is available. Thus, time plays an important part in the life of the farmer, as with any other enterprising individual. It enters into convenience and saving of expense. Those preferring the truck because it saves horses are to be commended

for their humane attitude and, at the same time, sensible one, for under ordinary conditions the horses can be put to some other task while the truck is doing the road work.

### Some Disadvantages

As to the disadvantages of the truck for agricultural purposes, as was stated before, poor roads head the list. There were a few who said they were unable to get competent drivers, and about one man in 35 said troubles due to mechanical defects presented the principal drawback. Other reasons, with the percentage of those replying declaring them to be the greatest disadvantages, were as follows:

Cost of operation, 17 per cent.

First cost, 5 per cent.

Inability to operate on soft ground, 9 per cent.

The question of poor roads is a serious one to the farmer who buys a motor truck. Even those who live on the best roads face certain periods of the year when their trucks must stand idle. Snow is one of the principal obstacles, while the farmer whose land is on certain types of road is more seriously handicapped in that heavy rains, spring thaws and other elements enter into his transportation problem. Consequently practically every farmer is forced to keep horses to supplement the truck when the roads are in poor condition. However, there remains the fact that at periods of the year when the roads are bad the horses are seldom needed for work in the field, and unless used for road work they would be standing idle.

In discussing the question of roads it was important to learn just what sort of highways the farmers who replied to the questionnaire were using. The survey showed that 29 per cent of the trucks travel usually on dirt roads only, 46 per cent on roads that are part dirt and part improved, and 25 per cent on roads which are wholly improved. On the average there were 10.7 weeks during the year when the trucks which travel only on dirt roads could not be used, 7.8 weeks when those which travel partly on dirt roads and partly on improved roads could not be used, 3.5 weeks when those which travel solely on improved roads could not be used.

In all, less than 25 per cent of the men found it possible to use their trucks every week in the year, and between 35 and 40 per cent reported that there were more than eight weeks during the year when they could not use their trucks. About one-half of the men with wholly improved roads stated that they could use their trucks any time during the year, but only 9 per cent of those with all dirt roads were able to do so, and there were more than eight weeks during the year when 55 per cent of these men with all dirt roads were unable to use their trucks.

As to cost of operation, the questionnaire showed that the costs varied from an average of 8 cents a mile for the one-half-ton truck to 20 cents a mile for the two-ton machine. Whether or not this cost is overbalanced by the saving in time, convenience and other advantages must be determined by the farmer himself to his own satisfaction. It is quite probable, however, that, although 5 per cent of the farmers consider this the greatest disadvantage, the same 5 per cent are included in those who consider time-saving the greatest advantage.

The first cost of the truck, in most cases, represents to the farmer an investment in added equipment. Few, especially those who have only from two to four horses, are able to sell their animals in order to replace them with a truck. On large farms, where horses are kept for road work only, this might be practical, but it would

be only in isolated cases. The costs of the trucks in the districts investigated varied from under \$1,000 to over \$3,000. This means that the farmer must be shown that his investment will yield a profit through the advantages set forth.

A majority of farmer truck owners still use horses for hauling in the fields and around their farm buildings. Many stated that they did not consider the truck practical for such work, but only a small percentage considered this the greatest disadvantage. When it is remembered that the smaller trucks predominate in these sections, it will be seen that they are not capable of hauling the loads that are sometimes necessary around the farm. Many others stated they did not use the truck for this work because they saw no particular advantage in doing so. The principal time consumed in hauling about the farm is in loading and unloading, and the percentage of the total time saved by the use of the truck for such work would be small compared with the time saved in road hauling.

### Hauling in the Fields

At the same time many reported that they used the truck to some extent for such work. It was shown in some instances that trucks would save time on hauls of 150 rods or more if the body was suitable for the material to be hauled, and no difficulty was experienced in obtaining traction over the fields. Figures were compiled showing that the men who do use their trucks for farm work hauled only an average of 45 tons of crops and 37 tons of fertilizer per year with them, while the average amount of crops hauled to market per year totaled 119 tons, and the average amount of fertilizer hauled on the road is 55 tons a year.

There are various other elements to be considered in selling trucks to the farmer. While time-saving in road hauls is an important factor, the farmer will want to know whether or not he can haul as much with the small truck, that apparently has proved itself the most practical, as he could with horses and wagon. The average load hauled with horses is about 1500 lb. The average load hauled with a one-half-ton truck is about 950 lb., while with trucks of from one to one and a half tons it is about equal to the average horse load. The average load of crops with two-ton trucks is 4950 lb., or about 10 per cent greater than the one hauled with horses.

There is, of course, the question of the two-way haul, but the survey developed that a comparatively small percentage of trips made to market returned with a full load.

It will be seen from these facts that the farmer truck owner is not at all bashful about pointing out the disadvantages of the motor truck in his particular business, but neither is he reluctant to give the good points. The fact that 95 per cent of the answers to the Department of Agriculture survey stated trucks were a profitable investment, even under present conditions, shows the farm offers a great potential market, especially for trucks of two tons and under.

A VERY thorough investigation is under way in the Metallurgical Division, Bureau of Standards, dealing with the microchanges which occur during the tempering of hardened steels. Some idea of the work involved in this investigation may be gained when it is remembered that it is necessary to take hardness measurements and make microscopic examination of all the specimens of each type of steel for each tempering treatment. Over 800 specimens are involved in the investigation and the time necessary for the mere polishing for examination is very considerable.

# Promotion by Careful Educational Methods

The man who is made a supervisor or foreman should know more than the factory rules and how to do his work. He must be given a knowledge of the reasons for all such rules and be possessed of power to break them in an emergency. Quality of leadership is often more valuable than skill.

By Harry Tipper

**T**HERE is a general complaint among business men that they are not securing from their organizations enough men of the broad judgment necessary to undertake supervisory work of considerable importance. This lack has become very visible, and the present problems have emphasized it, so that its real importance is being recognized more fully.

In the same way all through industrial establishments the character of the supervisory work varies very greatly and it is evident that the present methods of promotion do not provide a thorough basis for co-ordinated supervisory activities.

In almost all the establishments in the regularly recognized methods of selecting for promotion the main qualities demanded of the supervisor are those related to skill in connection with the work and a knowledge of the processes undertaken in the department.

Recently attempts have been made to provide some records of the qualities which might affect the ability to handle men and keep them working at a maximum speed, but these attempts have not worked the problem out thoroughly, and they have not considered in the least the elements of preparation of an educational character which should be undertaken in order to keep men of supervisory capacity actually prepared for the work.

The man who is working in association with other men at a specific job does not have the opportunity to use the capacities that are called for in a supervisory job, and his idea of the requirements of that job is almost entirely the result of the supervision under which he himself has been working. Lacking any education upon the matter except that which he can secure by his daily experience as a subordinate, the capacity of the man must be very unusual if he is able to step into a supervisory position and secure the fullest results therefrom.

The promotion methods to be employed in the industrial plant should contemplate the selection of the most likely individuals, their preparation, so that the elements of the supervisory job are understood, and their preliminary testing, so that the responsibility is put upon them as they prove their capacity of answering it.

The usual method of promoting in industry has contemplated only the education of the potential supervisor in the rules and regulations of the shop and its practices, the choice because of his skill and the development of himself by virtue of the responsibility that has been thrust upon him. These methods of promotion do not fulfill the requirements thoroughly.

The improvement in efficiency must come from the enlargement of the man's capacity to judge, to co-ordinate and to modify the general requirements to the individual item. It is not sufficient that the supervisor should understand the general system adopted in the factories, the general rules and regulations and the general methods governing the work. It is necessary that he should understand the reasons for these general systems and methods, so that he will be able to use his judgment in connection with them.

The sub-foreman, foreman and the factory supervisor have been very much neglected in the movements of applied education in the past twenty years. Much educational work has been developed in order to enable the subordinate in the office, sales, advertising, accounting and other departments to prepare himself for a position as supervisor, and this education has done a great deal in improving the outlook and developing the potential capacity in such departments. Even this educational work is not entirely adequate, and it still remains, as the dean of an engineering college remarked not long ago, that a student might get almost 100 per cent in many schools without having thought originally about the matter.

All educational work has a tendency to become dogmatic and to cause a reaction like that of the boy who, when his father was helping him with a mathematical problem, remarked, "That can't be right, because it's not done the way the teacher did it."

## Dogmatic Educational Methods

In the factory, with its centralized systems of inspection, its highly subdivided work, its array of rules and regulations, the natural education received by the subordinate is dogmatic in the extreme. Most of it is concerned with saying, "You must do this, and you must do it this way." There is little opportunity for an understanding of the systems and consequently the rules become bigger than the object of the rules.

The subordinate who has felt the lash of the slave-driver foreman and been annoyed by it is quite liable to imitate the same method when he is placed in the same position. It could hardly be otherwise, when his education has been confined to that method of supervision. The same thing is true of the necessities of the supervisory work in any other direction. The foreman and the sub-foreman and all direct supervisors of small groups of employees are the most important elements in the chain of management, as they are constantly associated with the subordinate workers and their methods

of supervision provide practically the whole idea of management as secured by the subordinate.

The supervisor who applies the rule strictly and without exception, regardless of the circumstances, suggests that the company regards the rules as unbreakable and subject to no modification.

The methods of promoting from the subordinate ranks to the supervisory ranks in the first capacity of supervision is of the utmost importance, and yet it has been almost entirely neglected.

### Promotion Methods

The promotion method should cover the following elements:

First, the relative skill of the subordinates in their work.

Secondly, their relative adherence to duty—that is, their attitude to hours, their concentration on the work, and so forth.

Thirdly, their qualities of leadership, either in the shop or out of the shop. These individuals vary greatly in their tendency to lead the gang or a small group. Some of them are constantly leaders in the activities in which the groups of workers engage, and probably their leadership can be discovered in the relaxing hours more usually than in the working hours.

Fourthly, the preparation of the subordinate by an education in the objects, the character and systems of the work, and his relative capacity as indicated by the response to that education.

All records that can be accumulated concerning the previous work of the employee are of value in determining his capacity, but they should be examined more carefully for the qualities they indicate than for the skill suggested, particularly the action of the worker in an emergency, such as the absence of the foreman, the necessity for a change not contemplated by the rules, or some other item depending upon the immediate judgment.

Sufficient notice should be taken of the activities of the workers to permit a record as to their relations and the leadership displayed in their outside activities, both as to the character and the extent of the leadership. This will give an indication of the potential qualities of the subordinates for the work of supervision, their capacity to co-ordinate the efforts of a group and to keep

that group working with reasonable content and efficiency.

The proper type of supervisor will not be secured, however, until the activities include a careful measure of educational work in connection with the job that is being done, the reasons for it and the value of it with particular relation to the systems employed and what they mean.

No man can work as well with things he does not understand as with things of which he is fully aware. Particularly is the supervisor hampered by any lack of understanding. If he must operate under rules that are mysterious and in connection with systems whose purpose is not fully understood, his decisions will be less valuable, his opportunity to co-ordinate will be limited and his ability to lead the group will be very much less.

Some work has been done along these lines in the last two or three years, but it has not become sufficiently general as a part of the industrial practice to enable the management to select from among the employees supervisors of real capacity for these jobs of intimate supervision.

It must be remembered in all cases as to methods of promotion that the potential capacity does not rise to the surface in connection with the job at all times. The limitations of the work do not provide much opportunity for this development, yet the potential capacity of judgment, decision and the ability to leadership may be more important than the skill in connection with the work.

It is particularly necessary to observe the character of the man's thought in its justice. The supervisor must be able to give credit to his workers for their work, encourage the development of improvements in their work and see that the glory and reward are apportioned in connection with the importance of the improvement. No amount of skill or capacity in the work will keep an orderly group in operation unless they believe the justice of the immediate supervisor.

No one system of records or observation will give the entire view of the subordinate's qualities constituting a probable capacity entitling that individual to promotion. The various records and the various activities and actions must be considered together in order that a true picture may be secured of the skill and quality of the man and not merely of his operating capacity.

## An Air Operated Jack

**A**N automobile jack operating by compressed air is useful in factories and garages where compressed air is available. The drawing of the jack shown in the accompanying cut does not make it clear which of the two heads of the cylinder is removable, but presumably it is the lower one. An 18-in. hollow handle connects to the cylinder at the bottom and extends up at an angle of about 30 deg. At the end of this handle are located an air cock and a hose connection. The piston is of the leather-cup type.

This jack, which is manufactured by the Avery Engineering Co., is made in two sizes, 6 in. and 8 in. The 6-in. jack has a piston head area of  $28\frac{1}{4}$  sq. in., and, with an air pressure of 100 lb. per square inch, will lift 2825 lb. The 8-in. jack has a piston head area of  $50\frac{1}{4}$  sq. in., and, with 100 lb. air pressure, will lift 5250 lb. By attaching a standard air gage with special dial graduations to the cylinder of the jack the latter may be used as a weighing device, indicating directly the weight

on the tires. The particular advantage claimed for this type of jack is quickness of operation. It is said to take only 5 seconds to raise a car off the floor.

## Air-Cooled vs. Water-Cooled Cars

THERE has been much talk recently regarding the air-cooled car and its merits as compared to the water-cooled variety. This, together with more or less positive statements that one or more manufacturers are soon to produce air-cooled cars in quantity and the well known fact that some prominent makers are doing intensive development work in this line, has tended to heighten interest in the subject.

There is no doubt that the air-cooled job possesses certain inherent advantages. These include freedom from freezing and such troubles as are involved in keeping a water cooling system in condition, rapid warming up upon starting, with consequent decrease in troubles from fuel dilution of lubricant, and probably some material saving in weight, most of which is not in the engine itself, but in the cooling system.

In theory at least there is no doubt that air-cooling can be made as effective as water cooling, for, since the air is the ultimate cooling medium in any case, the maximum temperature difference is also the same.

It then remains only to provide air fast enough and in sufficient quantity, and to bring it into close enough contact with an adequate cooling surface to accomplish the desired results. This involves some nice engineering problems, but they are certainly capable of ready solution.

The question of relative cost is an important one but one which it is not easy to answer in an abstract way. However, there appears to be reason to believe that the air-cooled power plant (with its self-contained cooling system) will cost little if any more than the water-cooled plant with its cooling accessories. It does not follow from the fact that the oldest and most successful air-cooled car is usually considered as belonging in the high-priced class, that all air-cooled cars must be in the same price class. Smaller and lighter cars costing about half as much per pound as existing air-cooled jobs are considered by some competent judges to be well within the bounds of possibility. There are indications that we shall have both high and low-priced air-cooled cars just as we now have cars in both price classes of the water-cooled type. There appears to be nothing inherently cheaper in either type.

The subject is fraught with many interesting possibilities. The present day motor car is not necessarily the ultimate type. We are certain to see lighter, more dependable, more efficient and more economical cars than we now have. There are many routes to these ends and few are bold enough to predict which route is the most promising.

It is practically certain, however, that at least one new air-cooled job will be given a real commercial trial within the next few months.

## Motorcycle Export Figures

EXPORTS of American motorcycles by months and by countries since Jan. 1, 1921, are published in this issue of AUTOMOTIVE INDUSTRIES. These figures are being compiled in this detailed form by the Bureau of Foreign and Domestic Commerce for the first time, and the data given brings the figures up to date.

Beginning with the October figures, AUTOMOTIVE INDUSTRIES will publish these monthly motorcycle export figures, showing countries of destination in the same table with the export figures of cars, trucks, tires and parts which it has published monthly for a number of years.

Exports have constituted a very large percentage of total motorcycle business during recent years, so that these figures should be of great importance to the industry. Available in this detailed form, they give a basis for study of foreign markets and examination of merchandising possibilities that will be of very definite value.

## Phantom Insurance

THE utter inadequacy of present automobile insurance methods was further attested the other day when a man in New York obtained a \$500 policy on a car which did not exist. The successful attempt

to secure insurance on a fictitious car was made by a representative of the office of the Commissioner of Accounts of New York City, in connection with an investigation of automobile insurance which is being made.

In addition to this policy the representative obtained from another insurance agent a policy for \$500 on a broken down chassis from which the engine had been removed.

Just what is to be the solution of the automobile insurance problem is not entirely clear, but that it is worth the study of every agency within the industry is certain. The co-operation of the insurance companies is a prerequisite to any immediate improvement and this is being accorded in certain instances. No real progress can be made, however, so long as loose methods of writing policies are comparatively common.

## Shortsighted Economy

IT was perhaps inevitable that Budget Director Dawes would make some mistakes in his commendable efforts to economize by pledging various Government bureaus not to use certain funds appropriated for specific purposes by Congress. One of these was made, we feel, when the Bureau of Mines appropriations for research work in connection with new methods of cracking petroleum oils in such a way as to yield larger percentages of motor fuel, and with methods of producing shale oil, were placed under the ban.

Those who have followed the trend of petroleum production and consumption in this country know that for several years domestic consumption has exceeded the domestic supply by very considerable and increasing amounts. The gap has so far been filled largely by imports from Mexico, but the production of Mexican fields has fallen off from some 600,000 to about 350,000 bbl. daily, and the best-informed engineers believe that the present Mexican fields are rapidly nearing exhaustion. If this proves true it is difficult to see how an adequate supply of motor fuel for this country can be maintained without imposing conditions (as to decreased volatility, for example) which it will be extremely difficult for the automotive industry to meet.

Under these circumstances it would seem to be short-sighted economy, to say the least, to curtail any governmental or other activity which is intended to help in the solution of a problem of so great import as that of furnishing an adequate motor fuel supply, not only in the distant, but in the very near future.

The recent abundance of motor fuel resulting from a distinctly temporary over-production of crude which could not well be stored, together with the general business depression and the consequent lower price of petroleum products, has apparently blinded many people who should know present conditions in the petroleum world. The Bureau of Mines is awake to the situation, but those in higher authority are either not awake or are indifferent concerning a matter of grave public concern. The day is not far distant when the automotive manufacturer will face a fuel situation which will make him no little trouble. The

Government as a whole can and must be made to appreciate the gravity of the situation, and its various agencies put to work with adequate funds to seek the solution. Let this be made clear to the cabinet members who are charged with handling matters of this kind, in particular the secretaries of the Interior Department and the Department of Commerce, and then see that congressional representatives appropriate the necessary funds.

## The Motor Bus Market

THE development of motor bus lines as aids to electric railways in solving particular transportation problems offers, perhaps, the best possible bus market of the immediate future. Such a market cannot open widely, however, unless the electric railways' interests are sold on bus transportation.

Sentiment at the recent electric railway convention in Atlantic City was largely one of antagonism to buses and could not be said to be encouraging. There was a strong undercurrent of progressive thought, however, which was distinctly favorable toward the bus, which recognized that in any given case the transportation system to survive would be the one which operates most economically and renders the best service to the public. In many cases such a system would include electric lines as well as buses, cooperating to furnish the most efficient arrangement.

A distinctly encouraging note is sounded along this line by the *Electric Railway Journal* in a recent editorial announcing the beginning of a monthly supplement devoted to motor buses, which said in part:

"It has been recognized for some time that this newly developed agency must be a permanent factor in urban and interurban transportation of passengers, and there has been an earnest desire on the part of most railway operators to be informed about its potentialities and accomplishments for the double reason of knowing how to meet the new agency in competition and how to use the new agency in co-ordination with existing rail systems.

"It is of value to make or obtain actual analyses of cost of operation of various trackless vehicle installations for the edification and education of the operators of these systems and for those who would undertake such operation. The leading operators of such systems, as well as railway men, are in thorough sympathy with such a program, for they both are anxious to know exactly where the bus is going to fit in ultimately in the passenger transportation business.

"The bus manufacturer is also vitally interested in all these matters. He wants to work closely with the operator to determine the fundamentals of design that will insure the most economy in operation. There must be considerable research and expenditure of money before there is any degree of finality in bus design principles. Some special designs have been developed, though some manufacturers still hold to the use of the standard truck chassis."

This desire for co-operation on the part of the electric railways is worth the attention of truck manufacturers. There is a definite opportunity for mutual profit in the working together of manufacturers and electric railway interests.

# Predict 1,700,000 Output in 1921

## Cars and Trucks Included in Figure

**Production Has Held Up Monthly  
Although November May  
Show Decline**

NEW YORK, Nov. 8—Conservative estimates of motor vehicle production in the United States for 1921 forecast a total of 1,700,000 passenger cars and trucks. This compares with 1,928,000 passenger cars and 348,000 trucks in 1920. Inasmuch as it was predicted that 1921 would be a "million car year," this output would be highly gratifying to the industry, for it would demonstrate conclusively that the sale of motor vehicles is established on a solid foundation regardless of general industrial conditions.

Shipments of motor vehicles for October were only 11 per cent less than for September, and they were 96 per cent of shipments in October last year, which showed a 26 per cent decline from September. The output last month exceeded general expectations. It marked the eighth consecutive month in which the production line remained practically stationary.

An even more striking illustration of the fact that there has been little deviation in production from month to month is found in a report of the business done by members of the Motor and Accessory Mfrs.' Association for September, which showed an aggregate gain of 1.9 per cent. There was a change for the month of only \$10,000 in the total of past due accounts, which aggregated \$4,358,000, an increase of 0.22 per cent.

Reports from Detroit are to the effect that manufacturers there, however, expect a certain reduction in output for November. Some of the companies making the higher priced cars believe it will be necessary for them to increase their output. Ford, whose production for October approximated 85,000, expects to build the same number of cars and trucks this month. Most truck manufacturers are confident that November business will be better than either September or October.

It is probable there will be a seasonal falling off in the number of sales for the next two or three months. Heavy demand for enclosed cars will

tend to hold up the volume of business as measured in dollars.

Attention of manufacturers has been centered of late on the used car problem, and a careful survey of the field is being made in an attempt to find a solution. After the investigation has been completed it is proposed to make recommendations to manufacturers which will be designed to minimize the evil, although it is not expected it can be eradicated. Overproduction has been one of the causes of trouble in the past and car makers will hold their future output more closely to an order basis than they have done in the past. There is hope that a large proportion of the used cars on the market can be disposed of before the early spring business begins. Reports of the number of these cars on the market are believed to have been very much exaggerated.

Another general reduction in the price of tires is expected to follow the action of the Firestone Tire & Rubber Co. in announcing a cut of 20 per cent on cords, 10 per cent on fabric and 10 per cent on truck tires. Announcement of this reduction merely gave formal sanction to a discount which had been given dealers some time ago. Other large manufacturers are going over their schedules, and it is generally believed they will meet the Firestone action.

Renewal of demand in the truck field is evidenced by the large number of price reductions on commercial vehicles which have been made in the past few weeks. Truck makers are now entering a period of competition as keen as that which has prevailed for several months in the passenger car field.

## Dunlop Stockholders Will Not Be Assessed

LONDON, Oct. 21 (*By Mail*).—Chairman F. A. Szarvasy of the Dunlop Co. categorically denies a report that the stockholders will be called on to meet an assessment on their holdings.

Reduction of capital is believed to be imminent. In one quarter it is reported that this excision will amount to half the ordinary stock capital. By reducing the nominal value of the £1 share by half and the capital stock by £6,500,000 it is said that resumption of dividends on both the preferred and common stock would be possible.

Meanwhile, it is officially declared that the position of the company is materially improved.

## Irvine Will Confer with Manufacturers

**Will Visit Automotive Makers in  
This Country Prior to  
World Tour**

WASHINGTON, Nov. 7—Preparatory to making a world-wide campaign for the development of foreign markets for automotive products, William I. Irvine, trade commissioner of the Department of Commerce, specializing in the automotive industry, will leave here Nov. 22, for conferences with representative automobile, truck and accessory manufacturers in a score or more cities of the country.

His plans call for a stay of two years and six months abroad. A large portion of this period will be devoted to an intensive cultivation of Far Eastern markets. The campaign which he will undertake is perhaps the most extensive ever considered by the Government in connection with assisting American manufacturers in the selling of their products in foreign fields.

### Will Visit Far East

It is Irvine's purpose to ascertain what the manufacturers want to know about Far Eastern markets by way of doing business with existing distributors. It is his intention to study highway conditions in order to show logical development of increased sales which may be looked for as a result of highway extension.

His knowledge of the various factors in the American automobile industry will be adapted to his studies overseas in order that American manufacturers may have specific information on which to base plans for Far Eastern markets. Export managers of domestic concerns will be questioned about credits, organization, territorial division, shipping practices, terms of contract and schedule of arrangement, advertising, service requirements, competition, and the nature of sales promotion work. The trade commissioner will have information for dealers abroad and will show them the way to estimate markets, selling practices, etc.

### Leaves in December

Irvine will probably sail from San Francisco in December. His itinerary calls for studies in Japan, Korea, Vladivostok, Manchuria, Mongolia, China, Philippine Islands, French Indo-China, Strait Settlements, Federated Malay States, Dutch East Indies; Islands of Java, Batavia, Borneo; India, including Burma and Ceylon.

(Continued on page 940)

## Winter May Exceed Trade Expectations

**Credit Conditions Easier—Much Unemployment Will Be of Voluntary Nature**

NEW YORK, Nov. 7.—With the coming of November there have appeared within the automotive industry evidences of an attitude of uncertainty and doubt as to what the next few months may bring in the way of business. AUTOMOTIVE INDUSTRIES has predicted frequently that trade will be better the coming winter than is generally expected. Nothing has appeared on the horizon to change this belief.

### Fundamentals Improving

The fundamentals of general business are steadily improving. While there undoubtedly will be a considerable amount of unemployment until spring it is not likely it will increase to a greater extent than has been the case in more normal winters. The outlook for the building trades, for example, is more hopeful than it has been in several years because a greater volume of building operations is under way throughout the country than at any time since the war.

It is becoming apparent that a considerable part of the unemployment for the next two or three months will be voluntary. Further reductions in wages are being fought vigorously in various trades and in many cases workers probably will strike rather than accept them. Their contention is that the decline in the cost of living has not been commensurate with the wage reductions proposed.

### Labor Situation Gratifying

The labor situation in the automotive industry is highly gratifying and the relations between employer and employee seem to be more satisfactory than in almost any other line. In some industries, however, employers are showing a disposition to take advantage of the present opportunity to force wages lower than their employees are willing to accept.

The industrial survey conducted by the United States Employment Service showed only a slight slowing up in automotive plants for October as compared with September. The decrease in employment was 2.8 per cent, or an actual falling off of 4883 in the establishments which reported. There was an increase of 1.01 per cent in employment by the 1428 companies in all industries reporting. These firms usually employ more than 500 workers each, or a total of 1,600,000.

The report shows that the industrial situation, as represented by employment conditions, showed a steady improvement in October. An outstanding feature was

the marked increase in the basic industries such as iron and steel, metal products and the railroads. These gains more than offset the decrease in the automotive industry which is a seasonal condition, and in the miscellaneous group, caused largely by the slackness in the shipyards. Reports from 231 of the principal industrial centers indicated that public improvements were absorbing some of the common labor released from agriculture, canneries and other seasonal activities.

Total employment in Detroit fell off only 192 last week, as compared with a decrease of 3900 the previous week. The monthly trade letter of the National Bank of Commerce of Detroit shows that 14.10 per cent of all lines of trade in that city were normal in October as compared with 11.25 per cent in September, making 85.90 per cent below normal as compared with 88.75 per cent the month before. A forecast of future business conditions made by the bank shows 42.31 per cent improvement in October as compared with 43.75 per cent in September and 44.87 per cent stationary as compared with 47.50 per cent the previous month. Bank clearings in Detroit for September, 1921, were \$406,698,000 as compared with \$416,711,000 in 1919 and \$561,592,000 in 1920.

(Continued on page 942)

## Expect Reorganization of Maibohm on Nov. 14

SANDUSKY, Nov. 7.—Reorganization of the Maibohm Motors Co. and the discharge of the voluntary receivership will be accomplished on Nov. 14, it is expected. On that date the sale of the property is scheduled to take place and it is expected that the reorganized company will take charge.

There has been no interruption of manufacturing operations and none is anticipated. The plan of reorganization comprises the payment of current obligations with preferred stock, and it is stated that nearly all of the company's purveyors have agreed to the plan and will become interested in the reorganized company. The assent and co-operation of the balance is expected.

### STAR MEETING POSTPONED

AKRON, Nov. 7.—The special meeting of the Star Rubber Co. stockholders, called for Nov. 5 to approve the refinancing and recapitalization plans, has been postponed until Nov. 25. The plan as outlined to the stockholders by letter provides for decreasing the capitalization of the company, exchanging existing \$100 par common stock for no par and increasing the directorate from five to seven.

### WALTHAM GOES TO BARRIE

TORONTO, Nov. 5.—The Waltham Motors Corp. of Canada, with head office in East Toronto, is to manufacture its motor trucks in Barrie, Ont., negotiations having been completed whereby it acquires the property of the Barrie Carriage Co.

## Sales Tax Adoption Seen in Near Future

**Effort Probable to Pass It As Substitute for New Revenue Bill**

WASHINGTON, Nov. 7.—Although the manufacturers' sales tax and a general sales tax have been rejected by the Senate and House, it appears that it ultimately will be adopted as a substitute for the new internal revenue bill. The manufacturers' tax of three per cent, sponsored by Senator Smoot of Utah, has the endorsement of the National Automobile Chamber of Commerce and various organizations of manufacturers. Senator Smoot offered it as an amendment to the tentative tax measure as a means of repealing special war assessments, including the excise tax.

### Immediate Move Likely

Statements made by several Senators and Representatives indicate that an effort will be made to replace the pending tax bill by a sales tax. The advocates of the sales tax plan say that it may be a leading issue at the congressional elections next fall. Business organizations and others proposing this method are expected to crystallize sentiment in the meantime.

The Senate has discarded the soldiers' bonus plan at this time. It is in accordance with the recommendations of the President. Chairman Fordney of the House Committee on Ways and Means and certain senators insist that it will be adopted at the regular session this winter. The President is opposed to this program, but representatives who are candidates to succeed themselves may override the objections for political reasons.

### Smoot Hopeful

As indicative of the trend of affairs, Senator Smoot said that talks with senators made it "quite evident that a sales tax will be imposed in the very near future, and every criticism that has been offered to the administration of the manufacturers' tax will apply as much next year, when it is said we will adopt a sales tax bill, as it would apply to-day. I have not a doubt in my mind that a bonus bill will be enacted into a law. In my opinion if the sales tax is to be imposed for the purpose of paying the soldiers' bonus, it ought to be put into operation as early as possible."

Ordinarily the internal revenue bill when revised endures during the four years allotted to each administration. However, the farmers' organizations and other groups are not entirely satisfied with the proposed measure, which will undoubtedly become a law late this month. The National Board of Farm Organizations has appealed to Congress in an effort to prevent the repeal of the excess profits tax and lowering of the surtaxes.

## Tire Trade Awaits Action on Prices

### Definite Stand by Manufacturers Following Firestone Cut Is Felt Necessary

AKRON, Nov. 7.—Possible tire price reductions occupied the entire stage in the Akron rubber industry during the past week. Firestone's cut of 20 per cent on cord tires and 10 per cent on fabrics and truck tires took the entire industry by storm and made up the reports of the industry for the whole week, and that without any tangible results.

Thus far none of the other large manufacturers have decided to follow his lead and at this time it is still uncertain whether they will do so. While the smaller Akron companies look to the Goodyear Tire & Rubber Co. and the B. F. Goodrich Co. as leaders who are to set the pace on tire prices at this time, these larger manufacturers turned toward United States to see what this corporation will do in the matter of following Firestone example.

#### Say Cuts Not Justified

Miller, Goodyear and Goodrich all state officially that further reductions in tire prices are not justified at this time and that they can only be made at the expense of wage and salary cuts, but feel that if other large manufacturers are to follow Firestone they will of necessity be compelled to do likewise.

The small manufacturers, such as the Mohawk Rubber Co., the General Tire & Rubber Co., the Swinehart Tire & Rubber Co. and those in the nearby cities express the same opinions. They do not feel that price cuts are warranted by present costs and that they will only cut when the large manufacturers compel them to do so.

Goodyear thus far has taken a determined stand against further reductions of prices. A week ago President E. G. Wilmer issued a statement in which he said he had not heard of any general movement to reduce tire prices and that Goodyear was not contemplating any such action. During the week, following the Firestone announcement, this was supplemented by a statement from the sales and advertising department that no steps have been taken looking toward any reductions and that under no circumstances will the company be stampeded.

#### Trade Disorganized

The Miller Rubber Co. toward the end of the week held a series of conferences regarding tire prices and costs but failed to come to any definite announcement regarding prices for the future.

If the other companies do not follow Firestone it will be the first time in recent years that any one large manufacturer has been permitted to cut the price and allowed to "go it alone."

The talk of possible tire price reductions as well as the Firestone announce-

ment has thoroughly disorganized the tire trade for the time being. Since the 20 per cent reduction was given the dealers confidentially during the latter part of October there has been a slowing up in business. Sales are reported to have fallen off materially and it will require either a definite statement by all manufacturers that they will not cut, or a cut to meet that of Firestone to put the trade back into normal position. But a flat refusal may not be sufficient without some additional guarantee of protection in case prices drop in the future.

That Firestone could make the cut more easily than the other manufacturers is pointed out by some of the others on the ground that Firestone's present business is largely that of the manufacturers, which is not affected by the cut to the dealers.

With the proposed cut tire prices are at the lowest point in the history of the automotive industry. The last cut brought them to the 1913, or previous low, level.

#### Kelly Tire Reduced

NEW YORK, Nov. 8.—Following the action of the Firestone Tire & Rubber Co., the Kelly-Springfield Tire Co. announced to-day price reductions on cord tires amounting to 20 per cent, on fabric 10 per cent, caterpillar truck tires 15 per cent, standard truck tires 10 per cent and tubes from 10 to 20 per cent. It was reported that the company would soon announce a special Ford size tire to sell at a popular price. Such a tire was put on the market several months ago and withdrawn.

### Automobile Blue Book Publishing Co. Sold

NEW YORK, Nov. 7.—The property of the Automobile Blue Book Publishing Co., which includes *Motor Life* and the *Blue Book*, have been sold to Joseph J. White of the Hill Binding Co. of Chicago. The sale was made for cash by the credit stockholders who have been operating the property for the past few months, in accordance with a resolution adopted by the stockholders, directing that the sale be made on Nov. 1. There will be an immediate distribution of the assets among the credit stockholders.

The property probably will be operated as heretofore both from New York and Chicago. It is likely the printing, mechanical work and distribution will be handled in Chicago. The business is in good hands and under the new ownership the *Blue Book* is expected to go forward to new records of usefulness.

#### BUTZEL BUYS HINKLEY

DETROIT, Nov. 7.—Henry M. Butzel purchased the property of the Hinkley Motors Co., valued at \$450,000, when it was sold at auction by the Security Trust Co. as receiver. His bid was \$300,000 and is subject to confirmation by the United States District Court. A conditional bid of \$10,000 for the Hinkley accounts also was made. Butzel stated the business of Hinkley Motors would be continued by a new company.

## Enclosed Car Show to Help New York

### Revival of Buying, Which Has Not Maintained September Level, Expected

NEW YORK, Nov. 7.—Passenger car dealers of the metropolis are looking forward to the enclosed car show, set for the week of Nov. 14, to break the mid-fall dullness which has settled upon the market and has made the day-by-day record of sales poorer than it was in September and somewhat below the retail movement of cars a year ago.

Definite October figures are not yet available but they are not expected to show a gain over September, except in the case of a few cars which have had notable price reductions or have brought out new models. Several distributors whose cars have remained unchanged in price and model for several months had an October business 10 to 20 per cent lower than September.

Enclosed car sales have dominated the medium and high price fields for the past two or three weeks and have made a good showing in the low priced classes. This fact, coupled with the statements of many prospects that they are going to wait to see what is in the show, which is now being advertised, leads the trade to expect good results from the show, in which dealers will have from two to four or six models each on display, according to the size of their spaces.

#### Sales Staffs Enlarged

A sensation of the week has been the salesroom show of the Maxwell Distributing Corp., which has presented the new Maxwell in a regular stage setting, attracting city-wide comment and big crowds of buyers and prospects. The show is being continued on its second and final week.

Several of the metropolitan dealers are enlarging their sales staffs for more intensive combing of the territory and nearly all of them are going thoroughly into salesmen's meetings and training of salesmen along scientific lines.

Used car prices continue low, with the market oversupplied and the trading problems of dealers who have not stopped trading acute. The truck business is keeping step with the gradual improvement in general business.

#### McKONE TIRE ORGANIZES

CHICAGO, Nov. 7.—The McKone Tire & Rubber Co. has been organized with general offices here and a factory at Millersburg, Ohio, to manufacture fabric and cord casings and inner tubes. A large part of the company's output is understood to have been sold in advance. A. L. Gustin is president of the company, C. W. McKone is vice-president in charge of production, L. C. Conley is secretary and treasurer, and O. L. Tweedy is sales manager. All are residents of Chicago.

## White Sales Show 20 Per Cent Increase

### October Business Is Better Than Average for Three Previous Months

CLEVELAND, Nov. 8—October truck sales by the White Co. were 20 per cent better than the average of the previous three months and the business indicates a general resumption of purchasing by the large industrial and distributing concerns in all parts of the country, according to company officials.

Walter C. White, president of the company, talked about affairs of the corporation and declared that August sales were better than they were in July, which was the low point; that September was a better month than August and that October outstripped September by a good margin.

Distributing concerns, packers and oil companies are purchasing trucks more readily than are manufacturing and producing interests. In his statement, White says that actual sales and orders for future deliveries have risen during October. At the plant production has gone up steadily since July 1.

Plans of the corporation provide for a gradual increase in production until Jan. 1, when it is purposed to have an output that will be more than twice as great as it was in July. Increased employee efficiency has been notable, for the greater production has been accomplished without the addition of a large number of employees.

#### Production Rearranged

Lately the company has availed itself of the situation to rearrange the plan of production. A progressive basis is used for the making of trucks, and that is attained by rerouting materials through the shops. No radical changes were made. It was brought about by a co-ordination of little improvement in methods and routing. As sales and orders increase and as production is speeded up to meet the demand, additional forces of workmen will be employed, but, due to improvements that have already been made, the production of trucks per man will be increased.

Collections are better to-day than they have been in several years. Approximately 90 per cent of the company's business is on a cash basis.

Inventories on Dec. 31, 1920, were placed at \$22,989,000 and this figure has been reduced several millions. Further cuts in the inventory are being made gradually. Bank borrowings have been reduced from \$8,750,000 on April 1 to less than \$5,000,000. The ratio of current assets to current liabilities is more than three to one.

#### QUALITY TRUSTEE NAMED

INDIANAPOLIS, Nov. 8—N. M. McCullough, an Anderson banker, was appointed trustee for creditors of the Quality Tire & Rubber Co., when credit-

ors attended a meeting and conferred with H. C. Sheridan, referee in bankruptcy. It was stated after the conference that stockholders of the company are progressing with a plan to raise \$200,000 by which they could meet obligations and arrange to operate factories of the Quality company here and at Elyria, Ohio.

## American Units Used in New Parker Product

MONTREAL, Nov. 8—A six-cylinder car known as the Royal Six has been placed in production by the Parker Motor Car Co., Ltd., of this city. The car is assembled from American units and is made in both the open and enclosed types. It sells for \$2,675 for the two, four and seven-passenger open types; \$3,275 for the sport type four-passenger car with California top; \$3,475 for the four-passenger coupé, and \$3,675 for the seven-passenger sedan. All models are on a 126-in. wheelbase chassis.

The engine is a Continental of 3½ x 5¼-in. bore and stroke, the clutch a Borg & Beck and the transmission a Warner three-speed, while the axles are Columbia. A Zenith carburetor is fitted. Ignition is by the Atwater Kent battery system and the starting and lighting is by Bijur equipment. Cooling is by means of a cellular radiator with pump and ball-bearing fan.

The frame is of Z section, 7¼ in. deep and with flanges 2½ in. wide. The running boards form an integral part of the frame members, being hot-riveted to the bottom flange of these members and also riveted to the vertical section at the front and rear where the running board curves up to meet the fenders at the top of the frame. Left steering is used. Five disk wheels with 33 x 4½ in. cord tires (non-skid tread for rear) is standard equipment. A very complete equipment is included in the price of the car.

## Acosta in Curtiss Wins Pulitzer Trophy Race

OMAHA, Nov. 8—Bert Acosta in a 400 hp. Curtiss navy racer won the Pulitzer trophy and a cash prize of \$3,000 here in the annual race for that well known aerial prize. The race was held over a triangular course 30 miles in length, which was covered five times.

Acosta's time for the 150 miles was 52 m. 9-1/5 s., which gives an average speed of 173 m.p.h. This is slightly below the record for the race, viz., 178 m.p.h., made last year by Capt. Corliss C. Mosley of the Army Air Service. The points of the triangular course were Omaha and Carson, Neb., and Loveland, Iowa, across the Missouri River. Second place in the race was won by Clarence Coombs of Houston, piloting a bright red colored plane known as the Cactus Kitten, whose time was 54 m. 7-3/5 s. Lieut. John A. Macready of the Army Air Service, holders of the world's altitude record, was third in 57 m. 27-3/5 s.

## Service Emphasized at Earl Convention

### Advertising Policy Outlined to Distributors at First Meeting With New Officials

DETROIT, Nov. 7—Addressing the first distributor convention of the new Earl Motors, Inc., Clarence A. Earl, president, emphasized the importance of taking care of customers, adding that a customer is a permanent asset and profits are legitimate only when a by-product of service.

To back up his selling organization he outlined an aggressive advertising policy and laid stress on the fact that he and his organization considered their distributors and dealers as members of their official family. Earl condemned the practice of justifying price cuts by eliminating advertising and accessories on cars as operating below the margin of safety.

The convention lasted for two days and was attended by all Earl distributors or their representatives. Hearty endorsement was given to the policy as laid down by Earl. Others who addressed the convention were John Fletcher, vice-president of the Fort Dearborn National Bank, Chicago; Kelly R. Jacoby, vice-president in charge of sales; D. Minard Shaw, advertising manager, C. D. Fray, and Charles Parlin of the research division of the Curtis Publishing Co.

An exhibit of the new cars was staged at the factory and a gratifying number of contracts for 1922 deliveries were made. Many sales were effected for immediate delivery on the new enclosed models.

## Amsterdam Will Hold Exposition Next Year

WASHINGTON, Nov. 8—Preliminary reports of an automotive exposition to be held in Amsterdam, Netherlands, in February and March of next year, have been made to the Bureau of Foreign and Domestic Commerce by Consul Frank W. Mahin, of Amsterdam.

The exhibition will be under the direction of and limited to the members of the Nederlandsche Vereeniging de Rijwielen en Automobielen-industrie, the Netherlands Automobile Society, but the regulations do not exclude foreign made cars.

#### NEW HEAD FOR ROCHESTER

ROCHESTER, N. Y., Nov. 7—LeRoy Kramer, formerly in charge of production for the Willys-Overland Co., Toledo, has been elected president of the Rochester Motors Corp. in addition to his duties as western representative of the T. H. Symington Co. Lorimer Dunlevy, formerly chief inspector of the Willys Corp. and later service manager of Rochester Motors, has been appointed works manager. C. J. Symington has been made chairman of the board.

## Service Convention Program Arranged

**Provides for Only Two Papers—  
Discussion Expected on Im-  
promptu Speeches**

NEW YORK, Nov. 7.—The program for the Service Managers' Convention which will be held here Nov. 15 and 16 under the auspices of the National Automobile Chamber of Commerce has been definitely arranged. The convention will be different from any previous convention in that instead of having a great number of papers read by various service executives there will only be two such addresses, the balance of the time being given up to topics for discussion on timely subjects and the service department. Some of these topics have been suggested in the program and the floor is to be entirely open so that anybody that wants to bring up any subject will have the opportunity.

Here is the program:

### PARTS SESSION

Address by prominent automobile official not as yet selected.

Report of Service Committee.

Topics for discussion.

How can we overcome the "pirate" parts evil?

Is it better to relinquish our parts service on obsolete models to underwriters?

What can be done to reduce the cost of parts to the owner?

Should parts prices cover tax and transportation so that owners can purchase parts at list anywhere?

### SERVICE POLICY SESSION

Topics for discussion.

Suggested improvements for Standard Service Policy.

Should special adjustments be based on time or mileage? If latter, on what basis?

How can we show more consideration for our customer?

### SERVICE SELLING SESSION

Address by Percy E. Chamberlain, presenting a plea for the flat rate plan.

Topics for discussion.

Which is better, the flat rate or some other way of charging for service?

Can piece work be applied in the garage to advantage?

Are service manuals and time studies on repairs by the factories helping dealers to give better service?

### GENERAL SESSION

Topics for discussion.

Should the factory provide facilities for training dealers' service men?

Should more information be given owners on making their own repairs?

How can we show dealers the sales value of well organized service?

There is no radically new subject to be brought up before the convention as far as the program is concerned, although there may be some such subjects introduced by the delegates to the convention.

It is probable that there will be a lively discussion on some points not included in the program. The subject of

## NORTHERN PACIFIC BUYS MACK TRAIN

ST. PAUL, Nov. 7.—The Northern Pacific Railroad has bought a motor train from the Mack Truck Co. for passenger service on the Gilmore & Pittsburgh line, a subsidiary of the main line in the mountain district between Armstead in Montana and Salmon City in Idaho. Economy and better and more frequent service are expected from the venture. The car will carry 18 passengers and baggage.

independent repair shops and the question whether the factories should cooperate with them or whether they should ignore them have been brought up at practically every convention held so far, and there is no doubt but what it will come in for a share of discussion at this time. The subject includes the question of allowing discounts to independent repair shops.

## Irvine Will Confer with Manufacturers

(Continued from page 936)

He will send back reports on current conditions and will try to make arrangements to have these reports continue. Instructions will be given representatives of the Government to give specific information desired by automotive exporters.

Many complaints have been received since the establishment of the automotive division to the effect that reports of consular agents are almost of no value owing to the lack of detail. Irvine means to correct this fault. These reports will be published in commerce reports, business papers and in the confidential reports for exporters, the latter to be sent in duplicate to exporters listed at the Department of Commerce. This service will be entirely without charge to American manufacturers, but all on the index must prove themselves bona fide automobile producers.

In his studies of the distributing system in the Far East and other countries, the commissioner will go to both seaboard and inland points to find out the conditions of roads, nature of country and the particular style of motor vehicle best suited for the purpose, freight rates, gasoline supply, garages, etc.

In an effort to compete with European manufacturers, who are cultivating Chinese markets, Irvine will go from Kalgan, China, to Urga, Mongolia, a distance of 700 miles. It was formerly a caravan route but recently has been devoted to automobile traffic. He will submit reports on conditions and value of equipment that will be required for motor transportation, and will recommend logical places for the establishment of dealers for American cars, and decide how the territory should be divided.

## Most Makers Join Government Agency

**Show Desire to Cooperate With  
New Division of Department  
of Commerce**

WASHINGTON, Nov. 7.—Although the automotive division of the Department of Commerce was established only two months ago, and completely organized Nov. 1, with a personnel of six people, it is pointed out that its major accomplishment has been the organization of 73 per cent of the entire automotive car and truck industry for cooperation with the division in furthering foreign trade interests. The division has also induced the Motor and Accessory Manufacturers' Association to consider the export field, to lay out foreign sales promotion plans and to assist in the selection of a committee to cooperate with the department.

In connection with the promotion of the aircraft industry, the division has secured a 100 per cent listing of the Manufacturers' Aircraft Association on the "Exporters' Index" and subscriptions to "Commerce Reports" and has arranged for a committee for cooperation. In the interest of clarification, the division has been partially responsible for the reclassification of export figures on a price and tonnage basis so that manufacturers can intelligently gage the class of exports comparable with their own production. It has also established trade information files for the purpose of collating specific automotive data of 109 automotive using countries.

Arrangement has been made with the National Automobile Chamber of Commerce to supply its members with data for a loose-leaf manual, containing concise export information for use of export managers of member companies and others in the industry. During the rail emergency, the division marshalled the resources of the truck and car manufacturers of the country and their trade associations for the purpose of solving transportation problems. It has also acted to prevent or delay the passage of legislation detrimental to the interest of American automotive manufacturers, contemplated in India, Switzerland, the Argentine and Canada.

## SEEKS RECEIVER DISCHARGE

STRATFORD, CONN., Nov. 8.—That the Liberty Motor Mfg. Co. has strong expectations of becoming a growing concern was stated in superior court here before Judge Frank D. Haines, when counsel pleaded that the City National Bank be discharged as a receiver, unpaid stock subscriptions amounting to an excess of \$17,000 be collected and a new loan be negotiated to pay off the mortgage of a like amount now held by the bank. The court denied a motion for an order for sale and continued the other motions.

## Essex Improvements Combined in New Car

### Model Does Not Represent Changes Made at Any One Time

DETROIT, Nov. 7.—The present Essex car, although quite different from the Essex of a year ago, has not been subjected to any great amount of change at any one time, but with the incorporation of the most recent improvements, the total changes amount practically to a refined model. Probably the two most important changes which have been put into effect are the new cylinder heads and the new pistons.

The cylinder head has been redesigned particularly with the idea of giving more combustion space over the exhaust valves. A pocket is provided in which the plug is placed. This completely isolates the plug from any location which is apt to be in the path of an oil throw and prevents fouling.

The intake passages are now arranged to give turbulence to the gases. The intake manifold now incorporates hot-spotting features, due to the arrangement of the water passages which are designed to permit higher temperature at certain points where it will assist in the evaporation of the fuel. The aluminum pistons are the diagonal-slit constant clearance type with three rings above the wrist pin instead of two as in the old model.

The pistons are split in such a way as to give a modified slipper effect. Due to changes in the chassis oiling scheme and the use of oilers instead of grease cups, the exhaust pipe has been altered to clear the oilers. A new muffler has been fitted incorporating a double cone expansion chamber and the springs have been regrated to improve the suspension. The Stewart-Warner vacuum tank is employed and the body finish is blue, giving an alteration in appearance of the cars.

DETROIT, Nov. 8.—Incorporating a number of simplified construction details, the Essex coach priced at \$1,495 is now being shipped to dealers. Priced at only \$300 more than the touring car, the new body is an exceptional example of economical manufacture. While incorporating up-to-date equipment and good workmanship, alterations in structural detail have made it possible to cut the cost of manufacture.

The new body is a two door design with individual folding Pullman seat in front and a three passenger seat in the rear. The cars are equipped with a dash control, ventilator, wind and rainproof windshield, sun visor, Dura crank handle, window lifts, four hinge doors, cord tires and the usual Essex chassis equipment.

#### MARTIN TESTING CARS

SPRINGFIELD, MASS., Nov. 5.—The Martin Motor Co. is trying out a third

model of its two-passenger car proposed to be manufactured here. From a competitive test of the three the most satisfactory will be chosen for commercial production. The special aim of the company is to reduce size and weight without loss of strength. Principal materials will be duralumin, aluminum and aluminum alloy. An exhibition will be made at New York, Boston and Chicago during the shows.

### Henderson Will Direct Martin Parry Branches

INDIANAPOLIS, Nov. 8.—R. P. Henderson, who has been vice-president and director of sales for the Western territory of Martin-Parry Co., has been transferred to a newly established office in Detroit, where he will be regional director of sales in charge of branches at Detroit, Cleveland, Columbus and Cincinnati. It is understood that other branches will be opened and included in Henderson's territory. Henderson has been prominent in Martin Parry affairs for several years, and was one of the sponsors of the Henderson Motor Car Co. Previously he had been identified with his brother, C. P. Henderson, in the Cole organization.

Mark Hamer, advertising manager for the company, has been transferred to the York, Pa., plant.

### Announce More Papers for S. A. E. Meeting

NEW YORK, Nov. 8.—The program of papers to be presented at the annual meeting of the Society of Automotive Engineers to be held here Jan. 11 to 14 will include the following papers in addition to those previously announced in AUTOMOTIVE INDUSTRIES:

Materials Session: Application of Chrome-Molybdenum Steel from the Consumer's Viewpoint, by C. N. Dawe, Chief Metallurgist of the Studebaker Corp.

Motor Truck Transportation Session: Economics of Motor Transportation, by M. C. Horine, engineer, International Motor Co.

The program of the meeting may be further extended to include papers on drop forging practice and on detonation studies, but this is as yet uncertain.

### Pilot Opens Branches in Distributing Centers

RICHMOND, IND., Nov. 7.—The Pilot Motor Car Co. will market its product in the major distributing points of the country through factory branches.

Two of the branches already have been established. That in New York, which is known as the Pilot Motor Co. is under the management of H. De Long Fry. The Chicago branch bears the same name and is managed by George F. Bates, formerly general sales manager of the All-American Truck Co. of Chicago.

It is purposed to open similar branches in Cleveland, Boston and Indianapolis.

## Arkansas Presents Promising Aspect

### Advancing Price of Crude Oil Contributes to Business Improvement

LITTLE ROCK, Nov. 8.—Business conditions in the automotive trade continue to hold out promising aspects over the State of Arkansas. Dealers are optimistic and are making plans toward further extending their trade. A number of firms are enlarging their quarters and many new firms have recently opened up for business.

The change in price of crude oil in the new oil fields in the southern part of the State has aided business materially in that section. Gasoline has been very cheap in this State for the past few months, but is advancing in cost. In fact, sales of gasoline and accessories have been better than sales of new cars. Crude recently went to \$1.50 a barrel at El Dorado and it is said that it may advance to \$2. Little Rock has been one of the cheapest gasoline cities in the United States from the standpoint of price.

Business conditions in Arkansas are better than in some other States for a number of reasons. The cotton crop is practically all gathered and most of it has been marketed, as a result of which there is some cash money in evidence.

All car dealers are thoroughly alert and are exerting every effort toward bringing in new trade. Buying is cautious but there is a marked lessening of the marked depression of several months ago.

The demand for enclosed cars is increasing with the approach of winter.

### Grant Motors Program Includes Enclosed Cars

CLEVELAND, Nov. 8.—The Grant Motor Car Corp. has extended the line of Grant Special models to the enclosed cars, a new sedan and coupé both selling for \$1,950 having been added.

The standard line of enclosed cars selling for \$2,450 is continued, but disk wheels, spare cord tire, nickel rim barrel headlamps, and front and rear bumpers have been added without increasing the price. The regular and special lines, both open and enclosed, are practically identical with the exception of some changes in the running boards and fenders, the difference in price being chiefly accounted for in the difference in equipment.

### DISTRIBUTORS ASK BANKRUPTCY

BRIDGEPORT, CONN., Nov. 7.—Hare's Motors of Connecticut, Inc., formerly selling agents in the state for the Locomobile Co., has filed a voluntary petition in bankruptcy in the United States Court at New Haven. The corporation lists its liabilities at \$59,302.55 and its assets at \$34,061.52. It had offices and a sales and parts station in this city.

## Winter May Exceed Trade Expectations

**Credit Conditions Easier—Much  
Unemployment Will Be of  
Voluntary Nature**

(Continued from page 837)

The easing of credit conditions is reflected in reductions of rediscount rates made by all Federal Reserve Banks. This has been reflected in corresponding reductions by member banks. The rate of the New York Federal Reserve bank now is 4½ per cent, which is the lowest on commercial discount since February, 1918.

A survey of general business and financial conditions issued in Washington by the Federal Reserve Board contains the statement that "some distinctly encouraging elements in the general business situation are to be noted. The outlook in the textile industries is among these. . . . Consumption of raw materials continues at a high figure and the total used in September was in excess of that reported for September 1920.

"In iron and steel an increase in both production and in unfilled orders has taken place, which although limited in amount, is regarded as of first rate importance marking the term from the low point.

"Better conditions are also reported in the lumber industry. . . . The activity in building has been particularly noteworthy because of its continuance beyond the time when the seasonal reaction would ordinarily occur.

"The better conditions in the agricultural districts combined with improved buying demand and the larger activities in manufacturing have naturally been reflected in increased activity in the wholesale trade.

"Retail trade has been well maintained in most parts of the country."

R. G. Dun & Co. in its weekly review of business, issued Saturday, said:

"Response to the constructive forces in the economic situation does not come quickly, but evidences of revival multiply. The recovery would be more rapid if fewer restraints were present, yet the gain is fairly steady and there is promise of its continuance. . . . While all statistical barometers do not reveal the improvement in business, records of production in several basic industries are distinctly better. . . . The trend of buying nearly everywhere is toward the staple and lower cost merchandise and the practically general resistance to price advances is added proof of the growing trend of economy."

Bradstreet's comment on the general situation said:

"Trade reports indicate rather more irregularity and some shifting of activities as November opens. For this varying weather conditions, the averting of the railroad strike, the apparent passing of the peak of fall distribution at big primary markets, the continuance of unsatisfactory prices for farm products at the West and a combination of lower prices and warm weather at the South are held variously responsible. The feeling is general that October as a whole was a fairly good month in wholesale and jobbing trades, that manufacture and industry made some notable forward steps and that unemployment decreased, but that collections rather tended to sag and that old past due pay-

ments, especially at the South, were not liquidated as well as expected."

The John V. Farwell Co. of Chicago says in a weekly review of trade:

"The wholesale dry goods business is manifesting a much greater activity than during the corresponding week of last year, the number and volume of road orders showing a large increase.

"General buying conditions have also improved it is reported. The larger retailers are making more complete commitments for spring in many lines. This is bringing about a much better and more normal percentage in a comparison of business volume with the number of orders received."

The monthly review of credit and business conditions, issued by the New York Federal Reserve Bank and dated Nov. 1, states:

"The volume of new building undertaken in the country as a whole in September was larger than in any previous month this year, and in this district was larger than in any previous month for which there are reliable records. This activity continued at a high rate during October.

"The production of iron and steel and of textiles shows a continued increase.

"The volume of the country's railroad traffic, especially shipments of manufactured articles, was larger during September and in early October than in any previous period this year."

The decrease in the number of idle freight cars continues steadily week by week. The decline last week was attributed largely to increased shipments of coal.

Interesting evidence of the better feeling among manufacturers is reflected in the large orders for new machinery to replace well worn equipment, which were placed by cotton manufacturers at the International Textile Exposition at Boston last week. It was reported that marked improvement in conditions has made necessary the speeding up of operations.

Probably the most significant indication of renewed confidence is the extraordinary strength of the bond market. Bonds of the United States and other governments have advanced rapidly in the past two weeks and their strength has been reflected in industrial bonds. The bond market is regarded as a barometer of industrial conditions.

The number of failures in October was 17 per cent greater than in September, but experience in past periods of depression has shown that the trend of business failures was steadily upward for months after business improvement began.

While there are no clouds on the business horizon which need give alarm to the automotive industry it undoubtedly is true that the coming months will bring a period of exceedingly keen competition in all lines of the industry.

### STANDARD DENIES RUMORS

PITTSBURGH, Nov. 8—Standard Steel Car Co. denies rumors that it would abandon the making of passenger automobiles and would concentrate its efforts on motor trucks. It states that "there is no change to announce in the policy of this concern."

## Shortening of Sales Is Reducing Output

**Factories Manufacturing Medium  
Priced Cars Reflect Hesitancy  
Shown By Dealers**

DETROIT, Nov. 7.—Reductions in manufacturing schedules at factories manufacturing medium priced cars indicate a gradual shortening of sales and a disinclination on the part of dealers to stock heavily against a winter and early spring demand. Although there are exceptions, most factories are already operating considerably under the October schedule and still further curtailments will be made.

Dodge Brothers, which has been operating on a 550 a day schedule since spring, will go upon a 400 a day schedule, Thursday, Nov. 10.

Buick has reduced operations to a three-day week basis, and Studebaker is also considerably below October marks.

Hupp is working upon a 10 car a day schedule.

Ford is continuing on the five-day week at the Highland Park plant, with a schedule approximating 85,000 cars set for November, but it is declared that the schedule is a flexible one and susceptible to sudden change, dependent on the market.

New models, new prices and other conditions are keeping most other factories on a strong production basis.

Maxwell, Chalmers, Oakland, Hudson, Essex, Packard, Cadillac, Chevrolet and Earl may be included as benefiting by these sales inducements. Maxwell is conspicuous in this list, the new models having created something bordering upon a furore in motor car circles.

## Firestone Is Reopened After 10 Day Shut Down

AKRON, Nov. 7.—The Firestone Tire & Rubber Co. has resumed plant operations after a ten day inventory shut-down on the basis of 18,000 produced a day. This is slightly less than the 20,000 which were on the production ticket when the factory was closed down.

The annual statement is being prepared and although official information is lacking thus far it is not unlikely that the company broke all previous production records and that a large part of the loss sustained last year through high priced inventory will be wiped out in the next statement.

Firestone has led in the production of tires throughout the past year, mainly because of the large amount of Ford business received.

### ANGLO-AMERICAN GETS SITE

TRENTON, ONT., Nov. 5.—A site of 32 acres has been granted by the rate-payers at this point to Anglo-American Motors, Ltd. Under the agreement the company will erect the first two units of its plant immediately.

## Islands Offer Field for Tractor Selling

### Manufacturers Advised to Turn Eyes to Philippine and Cuban Markets

WASHINGTON, Nov. 8—Officials of the Bureau of Foreign and Domestic Commerce are of the opinion that American tractor manufacturers should devote more time to the cultivation of Philippine and Cuban markets. Exports have fallen off sharply of late. Statistics show that there has been a decrease of \$618,950, due largely to the great slump in the demand for plows, cultivators and threshers, for which implements there has been thus far the best market in the Islands.

From April 1, 1921, complete tractors valued at \$34,378 have been sent to the Philippines, together with parts valued at \$31,945. Increase in the use of tractors has been remarkable. In 1917, 4 tractors were sold in the Philippines; in 1918, 6 were sold; and in 1919, 597 were sold, while during the fiscal year ended June 30, 1920, over 800 were sold. This great increase was largely in consequence of a tractor demonstration held at the Government demonstration farm at Alabang in October, 1919, where ten tractors were tested under the most exacting conditions. As a result of those trials, tractors won a place in Philippine agriculture.

Exports of agricultural implements to Cuba showed a decline amounting to \$270,669, for the first nine months of 1921. As tractors are not included in the total for 1920, and are included in that for 1921, the total decrease in exports of implements to Cuba, exclusive of tractors, is \$305,909. The value of tractors and parts exported is \$35,240, figures being for the period beginning April 1, 1921.

### LOWER MACCAR PRICES

SCRANTON, PA., Nov. 7—Price reductions have been made in several models of trucks manufactured by the Maccar Truck Co. The list follows:

	Old Price	New Price
Model L, 1½ ton.....	\$2,925	\$2,700
Model H-A, 2 ton.....	3,300	3,100
Model H-2, 3 ton.....	3,650	3,400
Model M, 4 ton.....	4,500	4,200
Model G, 5-6 ton.....	5,500	4,950

### STANDARD TRUCK DROPS

DETROIT, Nov. 9—The Standard Motor Truck Co. has reduced the price on its entire line:

	Old Price	New Price
Model 1-K, 1½ ton....	\$1,800	\$1,600
Model 76, 2½ ton.....	2,800	2,400
Model 66, 3½ ton.....	3,600	3,200
Model 5-K, 5 ton.....	5,250	4,400

### DAY-ELDER REDUCED

NEWARK, Nov. 8—Day-Elder Motors Corp. announces reductions ranging as

high as \$500 in the prices of its truck models. The list follows:

	Old Price	New Price
Model A, 1 ton.....	\$2,100	\$1,600
Model B, 1½ ton.....	2,300	2,000
Model D, 2 ton.....	2,750	2,400
Model C, 2½ ton.....	3,025	2,750
Model F, 3½ ton.....	3,750	3,150
Model E, 5 ton.....	4,250	4,250

### YUBA TRACTOR HIGHER

SAN FRANCISCO, CAL., Nov. 7—A revision upward in prices of the Yuba Ball Tread Products is announced by the Yuba Products Co.

	Old Price	New Price
12-20 .....	\$2,470	\$2,600
15-25 .....	2,945	3,100
20-35 .....	3,975	4,185
25-40 .....	4,417	4,650
Rodebilder .....	4,755	5,000

All prices are f.o.b. Benicia, Cal.

### FARGO REDUCES \$600

CHICAGO, Nov. 7—The Fargo Motor Car Co. has announced a \$600 price reduction on its 2-ton tractor, old price \$2,500, new price \$1,900.

### WETMORE REDUCES

SIOUX CITY, IOWA, Nov. 7—The Wetmore Tractor Mfg. Co. has reduced the price of its 12-25 hp. tractor from \$1,650 to \$1,585.

### CLEVELAND MOTORCYCLE CUT

CLEVELAND, Nov. 9—A new price cut of \$40 has been made on the Cleveland motorcycle, made by the Cleveland Motorcycle Co. This brings the price down to \$185. Electric lighting equipment is \$35 extra.

### NEW KENYON TIRES

NEW YORK, Nov. 7—The C. Kenyon Co., Inc., announces reductions ranging from 8 per cent to 10 per cent on its various sizes of cord tires and tubes. It also announces a new line of brown tubes the prices of which range from 30 cents to 90 cents less than its red tubes. The company announces a new line of heavy service tires and tubes. These tires range in size from 30 x 3½ to 36 x 6. The tubes for this line run in size from 30 x 3½ to 44 x 6.

## Validity of Gasoline Tax to Be Determined

HARRISBURG, Nov. 7—The constitutionality of the new state gasoline tax of 1 cent a gallon will be put to the test, according to state officials, as a result of the refusal of the Atlantic Refining Co. to pay the tax on gasoline sold for export, interstate commerce or manufacturing.

The company sent to Auditor General Lewis a check for \$39,426, representing the tax on gasoline sold for internal combustion or motor vehicle gas engine and similar purposes, but informed him it did so under protest, having been advised by counsel that the act was unconstitutional.

## Revenue Legislation Retains Excise Tax

### Bill in Conference Provides 3 Per Cent Despite Efforts to Remove It

WASHINGTON, Nov. 7—Efforts of Senator Townsend of Michigan to exempt automobile trucks and automobiles from the present 3 per cent excise tax failed and the Internal Revenue bill now in conference contains this feature, which is objectionable to the automobile industry. The Michigan senator used all available parliamentary tactics in order to secure consideration of his amendment which would strike out the proposal of the Senate Finance Committee to retain the tax. Senators opposing the exemption insisted that the Government needed this revenue and that buyers of trucks could well afford to pay it.

### Farmers Need Trucks

Senator Townsend said:

"I believe that automobile trucks and automobiles are two of the things that ought not to pay a tax, any more than any other vehicle of transportation should pay a tax. I think the prosperity of the country to a great extent depends upon these vehicles. They are already paying a heavy tax. The automobiles and automobile trucks pay, perhaps, a heavier tax than is paid by the various implements that are used by the people. They are practically supporting the roads; they are maintaining the roads, and in some of the states they are building the roads by the taxes that are put upon them.

"Every motor truck is used for a useful purpose, and not for pleasure. It is used in the business of the country and contributes very largely to the carrying on of the business of the country. There are hundreds of thousands, probably at least 200,000, of these trucks owned by farmers, and they are going to be more and more extensively owned and used by them for farm work."

According to Senator Penrose, chairman of the Senate Finance Committee, "if there is one feature of the tax bill that is not complained of, it is this. The tax furnishes a very substantial revenue; and if the Senate is going to begin to throw overboard taxes to this amount and of this character, we might as well stop entirely attempting to raise sufficient money for the requirements of the Government."

### Favors Exemption

In support of Senator Townsend's argument, Senator Heflin, of Alabama, said:

"The Senate should vote to exempt these trucks from the tax provisions of this bill. Surely if the great holding companies of the country can have their millions exempt and the profiteers can have \$450,000,000 handed over to them, the Senate can well afford to take the taxes off the automobile trucks. The automobiles that are used over the country generally should be exempt from the tax provisions of this bill."

Because of the widespread interest of the automotive industry in this question, Senator Townsend was successful in obtaining a record vote on the proposal to abolish the tax.

## Receiver Is Named for Lincoln Motors

### Company Files Voluntary Petition in Bankruptcy—Lelands Opposed to Move

DETROIT, Nov. 9—A voluntary petition in bankruptcy was filed in Federal Court here to-day by the Lincoln Motor Car Co. after a directors' meeting yesterday at which this action was decided upon by a vote of 6 to 3. The Detroit Trust Co. was appointed receiver by Judge Arthur J. Tuttle. Assets were estimated at \$14,800,000 and liabilities at \$8,237,280.

The directors who voted against the filing of the petition were President Henry M. Leland, Vice-President Wilfred C. Leland, and William T. Nash, secretary and treasurer.

#### Reorganization Considered

A statement by the Detroit Trust Co. says the assets include land, buildings, machinery and other plant investments valued at \$7,800,000; tools and merchandise, including finished cars and cars in process, valued at \$3,000,000; cash accounts and bills receivable amounting to \$800,000, and other assets valued at \$2,500,000.

The indebtedness includes merchandise accounts to the amount of \$1,868,000; obligations to banks, fully secured by indorsements, aggregating \$4,250,000; a mortgage for \$1,882,000 and land contracts involving \$237,280.

The trust company has taken possession of the company. The inventory which has been started will continue for several days and until completed manufacturing has been stopped. The service department of the factory will continue operations. Plans for a reorganization are under consideration.

#### Leland Wires Distributors

The following telegram sent by President Leland to Lincoln distributors voiced the undaunted courage of one of the "grand old men" of the automotive industry:

"Over our protest the board of directors of the Lincoln Motor Co. has consented to the appointment of a receiver. The Lincoln car during a period of unprecedented financial difficulties has demonstrated its supremacy in the automobile world, and while this receivership will compel a reorganization of the company we are starting with undaunted courage to build a greater and more united organization to carry the enterprise to complete success. We are confidently counting upon the loyal co-operation of our distributing organization and of the whole Lincoln personnel. We hope and expect that the receiver will carry on the manufacturing departments so that you can keep your business intact, and we will use every effort to hasten the time when the new Lincoln company can again give you the support that your splendid work deserves. With your advice and co-operation we are bound to succeed. Please tell your dealers and all our friends that the Lincoln company is taking a fresh start on the road to success."

Within a short time replies were received from distributors and dealers in all parts of the country, urging that the business be carried on vigorously and promising continued co-operation in the marketing of the car.

Ralph Stone of the Detroit Trust Co. issued the following statement in reference to the causes for the bankruptcy petition:

"The company perfected its models and incurred the initial expense necessary to place them upon the market just prior to the beginning of the period of depression which has adversely affected all kinds of business. This preparation involved the installation of factory machinery, special tools and the purchase of a large inventory at the peak of high prices. This placed a financial burden on the company which was more than its financial resources could properly sustain, in the absence of a volume of sales which, under conditions in the automobile industry and in business generally at that time, it was fully expected would be made. The management of the company was encouraged in this belief by the favorable reception of the new models by purchasers of high class automobiles, and this has been borne out by the fact that the sale of Lincoln cars has increased steadily, and for September and October has been the largest since the company started manufacturing."

#### Lost Stock B Control

No statement has been made by the Lelands covering plans for bringing about a reorganization of the company. They were the founders of the corporation and were understood to control a majority of the class B stock. There has been much speculation within the industry for several weeks concerning the fate of the company. A financial crisis was averted last year when the Lelands and the board of directors endorsed \$5,000,000 bank notes. In July a \$2,500,000 mortgage was authorized, of which leading directors purchased \$1,250,000. Recently another \$500,000 has been added.

(Continued on page 947)

## Seven Months' Goodyear Sales Total \$62,421,179

AKRON, Nov. 9—Net sales of the Goodyear Tire & Rubber Co. for the seven months ended Sept. 30, 1921, were \$62,421,179, according to a report issued to stockholders. Net earnings, available for interest and fixed charges, were \$6,838,486. Interest charges amounted to \$2,319,604, while other miscellaneous charges and adjustments, mostly losses on liquidation of fixed property and adjustment of inventories in subsidiary companies, aggregated \$1,123,028. The net surplus amounted to \$3,395,853.

The general balance sheet showed the company's ratio of current assets to current liabilities to be approximately 10 to 1. Its aggregate cash holdings, United States Treasury certificates and bank acceptances, totaled \$23,722,485.

Edward G. Wilmer, president of the company, in his remarks to stockholders, said sales of automobile tires during the first nine months of 1921 were in excess of the number of sales the same period last year.

## Gasoline Agreement Will Increase Output

### Standard Oil and Texas Co. Ac- cept Plan to Share Patents

CHICAGO, Nov. 9—Production of gasoline may be considerably increased by a business arrangement which has been entered into between two of the largest factors in the American oil industry. The Standard Oil Co. of Indiana and the Texas Co. have accepted a plan under which each has the right to operate under patents held by the other. These patents pertain to the pressure cracking of crude oil in relation to the manufacture of gasoline and other petroleum products. Furthermore, and of greater importance, either company may license others to operate under any and all of the patents under an agreed division of royalties.

The granting of licenses to other companies to use these patented processes, through which the greatest percentage of gasoline is produced from crude oil, should result in benefiting the oil industry as a whole and also increase the supply of petroleum products essential for the use of internal combustion engines. Larger production of gasoline should prove a stimulus to the automobile industry.

The Standard Oil Co. of Indiana owns Burton, Humphreys, Clark and other patent rights, while the Texas Co. holds the rights on the Adams, Holmes, Manley and other patents. Through the Burton process, which was largely developed by Dr. William Burton, new president of the Standard Oil Co. of Indiana, nearly 50 per cent in gasoline is obtained from crude oil, whereas in 1910 the average was about 11 per cent and in 1920 about 26 per cent. The Standard of Indiana is one of the principal refiners and the Texas company one of the largest producers of crude oil as well as a large refiner.

## Van Briggie Executives Plead Guilty to Charges

INDIANAPOLIS, Nov. 9—L. H. Van Briggie, former president, and Harry S. Rominger, former treasurer of the Van Briggie Motor Devices Co., pleaded guilty in Federal Court here to the use of mails to defraud. They previously had entered pleas of not guilty. The request that date for sentence be changed from Nov. 7 to Nov. 14 was granted in order that Van Briggie might return to Detroit to arrange his affairs.

Charles A. Taylor, former general manager of the Van Briggie company, who was also indicted with Van Briggie and Rominger, was in court but did not change his plea of not guilty. It is understood that the district attorney will petition the court to dismiss the case against him.

## Implement Trade Advances in Texas

**Predicted That Spring Will See 35  
Per Cent Increase Over Same  
Period in 1920**

DALLAS, Nov. 8.—The farm implement business in Texas, which has suffered an unprecedented slump during the past thirty months, is assuming a rosy hue and will show material increases in the spring of 1922, according to dealers from all sections of the State. It is generally predicted that the increase will be 35 per cent over the business for the spring of 1921, when a good increase was shown over the preceding year.

The dealers make these predictions after a close survey of the situation, personally and from reports of salesmen who are patrolling every nook and corner of the State. There appear to be no favored spots. The dealers alike are saying the business is on the upgrade and that the increases are coming.

### Farmers Over-bought

The cause of the phenomenal slump in the farm implement business according to practically every dealer in the State was due to two things:

First—Poor crops and money stringencies.

Second—The farmers over-bought themselves in 1918.

As to the first, the retailers say the situation is materially better now. There is more money in circulation and the farmers are in a better position to buy. The farmers are diversifying their crops and this calls for a variety of implements.

Of the second, the dealers say that the implements bought three years ago, many of them at least, are gone and must be replaced. They state that the farmers are making inquiries and that farmers do not make inquiries about implements until they need them and when they need them they are going to buy.

### Normal Conditions in 1923

From south Texas dealers, who sell to south and east Texas farmers, the predictions for retail farm implement business in the spring of 1922 are especially glowing and the dealers are more than encouraged.

The notes of better business, however, are not being poured out by south Texas dealers alone. The Dallas farm implement dealers see better business ahead. In fact, they have been enjoying a pretty brisk business for several months. Unlike the Houston dealers they have a large territory to cultivate and a great variety of implements to offer.

It is said that the farm implement business so far as Dallas is concerned, is much better at this moment, and has been for months, than the business in south Texas because of the varied territory sold and the fact that the grain, cane and north Texas and Oklahoma

### ALTHOUGH DURANT DIRECTOR, MINIGER SAYS HE WILL NOT LEAVE WILLYS

NEW YORK, Nov. 9.—The following statement has been received by AUTOMOTIVE INDUSTRIES from C. O. Miniger, president of the Electric Auto-Lite Corp. and vice-president of the Willys Corp., whose contract with that corporation will expire, it is understood, next July.

"There is positively no truth in the rumor that I am to leave the Electric Auto-Lite Corp. and my Willys connections to go elsewhere. I have never considered it in the past and am not considering it now. The statement which has gone forth is absolutely false. I have accepted a directorship in Durant Motors of Indiana and probably will become a director of Durant Motors, Ltd., of Canada, but that will only strengthen the business position of the Electric Auto-Lite Corp."

Miniger's election as a director of Durant Motors of Canada has been announced in the Dominion. Up to this time he has not been elected a director of Durant Motors, Inc., parent of the various Durant subsidiaries.

It was stated in AUTOMOTIVE INDUSTRIES of last week that he would leave the Willys organization some time before Jan. 1.

cotton farmers made more money than the rice, vegetable and east or south Texas cotton farmers. The farm implement business in Dallas is 67 per cent normal right now. An increase of 35 per cent in the spring of 1922 over the spring of 1921 would make the business at least 82 per cent normal, and with a good grain and cotton crop the business would probably get back to old strides in the spring of 1923, while it will probably be a year later with the south Texas dealers.

## Portland Continues Good Trade Record

PORTLAND, ORE., Nov. 8.—A surprising and most satisfactory continuance of good business has marked the automobile market in Portland during October. The first few days of the month were unusually good, due to the fact that another discount in the State license tax for the year went into effect at that time. After that, however, there was a falling off of business, judging from the daily reports of license applications and the statements of leading automobile men here.

After but a brief lull there was an improvement in business, however, which continued throughout the month. Drops in prices of a number of cars, bringing out of new models and continued fair weather are given as the causes, in addition to the general improvement in the tone of all business.

## Terminal Delays Costly in Britain

**Engineer Urges Adopting of Im-  
proved Loading and Un-  
loading Apparatus**

LONDON, Oct. 29 (By Mail)—W. Williamson, engineer to Walker Bros., makers of Pagefield trucks, in a paper at the Truck Congress during the recent Olympia truck show dwelt on the problem of reducing terminal delays—the greatest bugbear of road automotive traction in Britain.

The problem of reducing delays, terminal and intermediate, he pointed out, divides itself into three sections:

1—The provision of specially equipped bodies facilitating the rapid handling of loads in detail or the provision of detachable bodies with suitable mechanism enabling them to be run rapidly on or off the chassis.

2—The provision of special equipment at the motor user's loading stage, as, for example, cranes, ramps or runways.

3—The special equipment of the chassis itself, as, for example, the fitting of gear for operating a tipping body, an overhead crane for loading purposes, or a winch operated by the engine power.

A 7000-lb. truck at present averages about 30 shillings a day for standing costs, which is equivalent under normal exchange to 8 cents a mile per 90 miles daily; and 12 cents for 60 miles per day. This represents a constant loss of 4 cents a mile, and on a yearly mileage of 12,000 is equivalent to a cost of £100. To equip a truck with a gantry frame and runway and interchangeable skip, bodies would cost about this sum, yet it is the exception here to find a truck so fitted; at most, one sees only a power windlass and occasionally a derricking crane slung at the back.

### NAME BUCKEYE RECEIVER

INDIANAPOLIS, Nov. 9.—On application by John W. Lambert, one of the principal stockholders and creditors of the Buckeye Mfg. Co. of Anderson, Judge Ellis Madison of the Superior Court has appointed Linfield Myers, president of the Madison County Trust Co., receiver for the Buckeye company. The plaintiff alleges that the liabilities approximate \$175,000 with assets in excess of that amount. The condition of the tractor market is said to have been the cause of the receivership. The company originally manufactured automobiles.

### AUBLE SELLING DURANT

CHICAGO, Nov. 7.—W. C. Auble, under the firm name of W. C. Auble Motor Co., has been awarded the Durant franchise for the distribution of the new Durant cars in the Chicago territory. Territory included in the Auble contract consists of Illinois from Springfield north, northeast section of Indiana, river counties in Iowa to and including Dubuque, four counties in Missouri and southwest Wisconsin.

## G. M. Is Testing Air Cooled Motors

### Production Delayed Pending Conclusion of Preliminary Work on New Models

NEW YORK, Nov. 9.—The recent strength of General Motors stock in Wall Street is attributed by financial writers for the New York papers to a report that the corporation soon will bring out an air-cooled engine which "will revolutionize the industry." The fact that General Motors proposes to put an air-cooled car on the market has been known within the industry for months but details have been withheld pending the completion of experimental work.

In order to set at rest the various rumors in circulation about General Motors plans in connection with air-cooled cars, the following statement was made to AUTOMOTIVE INDUSTRIES by Pierre S. du Pont, president of the corporation.

"The General Motors Corp. has been experimenting for several years past with air-cooled types of motors, as also it has been developing other types of motors and improvements incident to automotive practice. This work is conducted by a subsidiary of the corporation known as the General Motors Research Corp. and located in Dayton, Ohio, under the direction of C. F. Kettering.

"The development of air-cooled motors has reached a point where experimental models have been completed and exhaustive studies and tests are now being conducted.

"As to when production will commence, what manufacturing divisions of the corporation will develop and sell these models, all this, of necessity, must be held in abeyance until such time as the experimental development work is finally completed and the corporation is assured that its new products, which it must necessarily stand sponsor for, are everything that might be desired."

## Farmers in Northwest Soon to Start Buying

SEATTLE, Nov. 9.—Farmers of Washington, Oregon and Idaho are going to spend the proceeds of bumper crops in part for automobiles and automotive supplies. This is evidenced by a survey made by representative farm journals of the three states—the *Washington Farmer*, *Idaho Farmer* and *Oregon Farmer*. Each of their 6,000 subscribers received a questionnaire covering his prospective purchases of all kinds. On the basis of returns an average was computed and applied to the total of 158,600, which is the estimated number of farmers in the three states.

In this way it is figured 7206 farmers will buy automobiles in the near future. No fewer than 38,249 will buy tires soon. Purchasers of dry batteries number

19,130, while 3085 need storage batteries. Accessory shops in the three States may expect to sell 5727 carbureters before many weeks are past. There will be 2352 motor trucks disposed of, also 828 tractors and 746 tractor plows.

Other accessories and gas engine equipment which will be sold, according to the survey, include 2542 magnetos, 15,050 piston rings, 4771 roller bearings, 5564 shock absorbers and 2688 gas engines.

## Owen Magnetic Property Is Sold by Receivers

WILKES-BARRE, PA., Nov. 9.—Negotiations for the sale of the plant of the Owen Magnetic Motor Car Corp., at Forty Fort, near here, were completed to-day and merely await confirmation of the court. The sale was conducted by the receivers. The ground and buildings were purchased by Frank F. Matheson, the local Dodge dealer, and a former member of the firm of Matheson & Co., makers of the Matheson Silent Six. He is a brother of C. W. Matheson, who is general sales manager for the Dodge Brothers Motor Car Co. The purchase price was \$94,000. Matheson announced to-day that he intends to remodel the plant and convert it into a garage. The main building is 80 x 600 ft., and there is an additional wing 80 x 200 ft.

The machinery was sold to A. Lamberg of New York for \$102,000. The cars in stock, patterns, drawings, jigs and materials in process were purchased for \$18,700 by D. S. Dryer of New York.

## Low Prices Clean Up Texas Used Car Stocks

DALLAS, Nov. 9.—There was no sagging in the automobile business with the retail dealers during the first week of November. In fact the retailers did more business during the first week of the month than they did during the closing week of October.

While low priced cars were selling, the week appeared to be the best of the year for the higher priced cars.

Owing to the fact that retailers, many of them at least, put on unique sales, and quoted prices that were astonishing, there was a large number of used cars moved. The Dallas dealers were not alone in the pushing of such sales. Retailers throughout Texas appeared to adopt the week as "used car" week and advertised and sold them extensively. Several dealers report they had cleaned out their cars taken in on trade.

## S. A. E. SECTIONAL MEETING

MINNEAPOLIS, Nov. 9.—A dinner meeting of the Minneapolis section of the Society of Automotive Engineers was held here in the Manufacturers' Club. Speakers were Professor A. F. Moyer on Rotative Balance, A. H. Bates on Engine to Ground Power Absorption in Tractors, and F. E. Kenaston on The Relation of the Banker to Industry.

## Australia Lowers Duty on Tractors

### Tariff Reduced from 40 to 10 Per Cent—Caterpillar Type Favored

LOS ANGELES, Nov. 8.—The caterpillar tractor is to be greatly favored by the new Australian tariff and indications are that America's exports of tractors will hereafter be largely confined to this type. The Australian Parliament recently adopted an amendment to the tariff act, providing that tractors "which are not produced in Australia" shall pay a duty of 10 per cent instead of the 40 per cent duty hitherto charged. The intention of this amendment was to exempt caterpillars, but the decision as to which tractors shall be taxed at the reduced rate has been left to the new tariff board, which has not yet been constituted.

### Extremes of Weather

Conditions greatly favor the use of the caterpillar in Australia. The character of the soil differs so much that only a machine which can work in all kinds of land will prove economical. Then, too, Australia has extremes of wet and dry weather, with mud so deep and sticky in wet weather as to disarm a round wheel tractor, and the ruts so deep as to embarrass it when the ground begins to dry. In moderate weather, when the ground is soft, dry and flat, the round wheel works well, but even then is likely to strike patches of clay or other material which impede its operations.

## New Cole Series Shows Refinements in Design

INDIANAPOLIS, IND., Nov. 10.—A new Cole series has been announced embodying twenty-four different improvements, mostly in detail design, equipment and finish. Perhaps most important among these improvements is a re-designed aluminum piston of the constant clearance type. Thermostats are now incorporated in the cooling system, and the design of the oil pump has been improved. The clutch has also been re-designed and now is fitted with a clutch brake and is easier to operate, requiring less pedal pressure.

The spring shackles are now adjustable; the radiator is mounted on coil springs and the frame has been materially stiffened by the addition of tubular cross members. The strength of practically all structural parts has been materially increased and anti-rattle features have also been given considerable attention, heavier anti-squeak material being used wherever necessary. Improvements have also been made in the trim and in the finish of both chassis and body. The general specifications of the car remain the same and there has been no change in price.

## South Africa Will Make Truck Bodies

### Machinery Also Being Imported for Greater Manufacture of Spare Parts

JOHANNESBURG, Oct. 5 (*By Mail*).—The general aspect of the automobile trade is showing decided signs of improvement both in rural districts and elsewhere. Better sales records are being shown by most dealers and an optimistic spirit prevails. The tire companies are piling up sales records that bid fair to pass the 1919-20 mark.

Sales can be made every day but most tire companies and dealers find that the supply does not cope with the demand for popular sizes. This especially refers to cords. Such a condition applies to the Union only. There does not seem to be much change in Rhodesia but further north in Nyassaland there is a period of acute depression that is threatening the budding motor industry there.

Machinery is now being imported from the United States and Europe for the manufacture of steel bodies for trucks in Johannesburg and the necessary plant is also being imported by a number of firms for the manufacture of spare parts for all classes of automobiles.

In some cases the parts turned out by the different engineering works are produced in quantities and sold to dealers who stock them regularly, whereas in former days service stations had to rely on imported articles. Instances have occurred when orders have been placed with local firms for certain parts and the results were so satisfactory that orders were given immediately for large quantities.

This applies, of course, to comparatively simple jobs but as the industry expands the manufacture of spares and parts will expand accordingly so that in time the importation will come to an end except in cases where it will be cheaper to import the more complicated sections of engines, etc.

## Receiver Is Named for Lincoln Motors

(Continued from page 944)

The directors, it is understood, refused to sell the remaining authorized bonds or any unused company property. The Lelands held out for this alone, although they had surrendered control of their class B voting stock to assure previous financing. A glimmer of hope came last week with an offer of help from New York interests but this source of relief failed.

Universal regret is expressed in all quarters of the industry because of the financial difficulties which the Lelands have met in their new enterprise which had its inception in August, 1917, when the Lincoln Motor Co. was incorporated with a capital of \$1,500,000 to manufac-

ture Liberty Motors for use by the United States Government in the European war. This company was supplanted in January, 1920, by a Delaware corporation formed to manufacture a high quality car. The plant, which was erected in Detroit at a very large expense, is one of the finest in the country.

The Lincoln car was placed on the market at an exceedingly inopportune time, making its appearance almost simultaneously with the beginning of the period of deflation. Considerable difficulty was experienced in getting under way, but once the merits of the car, which was designed by the man who had most to do with the building up of the Cadillac, were recognized by the public, sales steadily increased and the business would have been on a solid foundation but for the fact that it had been necessary to incur heavy obligations to put it on the market.

There is no man in the industry who is more generally and genuinely admired and respected than Henry M. Leland. He has been a bulwark of honesty and good faith and has exerted a powerful influence for honest manufacture for 20 years.

As soon as it became generally known that the company had been forced into bankruptcy, the hope was expressed in all quarters that the Lelands would be able to work out a reorganization which would leave them in control.

In addition to 160,000 shares of class B stock of no par value, the company has outstanding \$8,000,000 in 10 per cent cumulative class A shares with a par value of \$50. This stock was first offered to the public in January, 1920, at par and is listed on the Detroit stock exchange. It has been weak for the past two or three weeks on rumors of reorganization of the company.

## Franquist Obtains Piston Injunction

NEW YORK, Nov. 9.—An order for preliminary injunction has been granted by Federal Judge Learned Hand in the Federal Court for the Southern District of New York to G. E. Franquist, owner of Patent No. 1,153,902, restraining Walker M. Levett Co. of New York from manufacturing and selling pistons alleged to infringe the patent in question. The restraining order was broadly effective that date, but suspended until Jan. 1, 1922, in the case of pistons undelivered on one particular contract.

Franquist's invention makes provision for a smoothly fitting piston skirt at all temperatures. The skirt is slit in such a manner as to fit when cold and to be compressible under uneven expansion of piston and cylinder.

## LEE COUNCILMAN INJURED

NEW YORK, Nov. 10.—Lee Councilman, former sales manager for the Chalmers Motor Car Co., was dangerously injured when his car was struck by a Long Island Railroad train at Beechhurst. His recovery is expected, but he may lose the sight of one eye.

## METAL MARKETS

On the surface the steel market presents an appearance of calmness which might be mistaken for placid serenity when, in fact, it is but the lack of incentive, resulting from utter apathy on the part of consumers, that tends to maintain prices at nominally unchanged levels.

The sheet market is once more headed toward the same state of affairs which prevailed a few months ago when producers eagerly vied with one another to corral every desirable order in sight, maintenance of reasonably satisfying production schedules being a more vital consideration than maintenance of price. Then the outstanding explanation was that many mills were willing to take losses temporarily so as to stimulate demand and bring consumption back to more normal proportions. In the case of a large number of producers prices that a few months ago would have entailed a positive loss may now be sufficient to make both ends meet. This is due not so much to the slight economies that have been effected but rather to the downward adjustment in inventory values.

If cold-rolled strip steel which is now generally quoted at \$5 a ton higher than it was a few weeks ago, forms an exception, it is due the belief of producers that just as much business will come out at the higher levels as would at the former prices. Passenger car builders who are using this kind of steel in the making of fenders are not likely to have recourse to full-finished sheets because of this advance, which, moreover, brings cold-rolled more into line with the price for hot-rolled.

Expressive of the entire situation is the fact that non-integrated sheet mills which depend for their supply of sheet bars on other producers, are able to place orders for these once more at prices practically unchanged from those that existed prior to the market's advance on Sept. 15, to \$32. Quite a few of these sheet mills still have tonnage of bars coming to them on account of \$29 @ \$30 contracts and are specifying against these. The market for cold-drawn steel bars is decidedly soft.

Pig Iron.—Modest tonnages of malleable are being bought by automotive foundries in the Middle West for shipment over the remainder of the year. The market is quiet, consumers being in a "hand to mouth" mood of buying.

Steel.—Sales of cold-finished steel bars are reported to have been made at as low as 2¢ base. There are said to be resale offerings of automotive screw stock at that level and mills have been meeting it in some instances, although the market is nominally quoted at 2.25¢, base. The leading builder of low-priced passenger cars is reported to be in the market for a tonnage of forging bars. Some automotive orders for cold-rolled strip for shipment over the next three months are reported to have been placed.

Aluminum.—All sorts of rumors are circulating. One has it that the domestic producer is meeting the low prices quoted on European ingots, though the official quotation has undergone no change. Another report had it that large tonnages of cheap metal and sheets passed into consumers' hands. None of these can be verified. The market continues to bear every outward evidence of being deserted by buyers.

Copper.—Producers are once more making an attempt to elevate prices but there is plenty of copper to be had at below 13¢.

## INDUSTRIAL NOTES

Hayes Wheel Co. has established a sales and service branch at 250 West 54th street, New York City, for the purpose of supplying the eastern territory and export division. Donald Ganiard will leave the general offices of the company at Jackson, to take charge and will be assisted by L. J. Curry, formerly with the Sales Service Co. at Philadelphia, as sales manager, and F. R. Symonds of the sales and service division of the Hayes Company at the home plant, to be in charge of stock, shipping and receiving.

Dewey-Collins Co., with offices in New York City, has been formed to act as manufacturers' sales agents. The company is composed of Martin A. Dewey, Jr., who formerly was with the Gemco Mfg. Co. and later sales manager for the Buckley Ralston Co. of this city and Thomas A. Collins who formerly was with the A. J. Picard Co., of New York. They already have taken on the products of several manufacturers.

Fuller & Sons Mfg. Co., Kalamazoo, will go into regular production of passenger car transmissions. During the dull period the company devoted the entire energies of its engineering and experimental departments in the development of two types of passenger car transmissions and is now prepared to produce the initial models. The styles will be suitable for both lighter and larger cars.

Quaker City Rubber Co. of Philadelphia has moved into its new modern five story building in Market street which will house the offices and sales rooms. Ample space has been provided to facilitate the movement of orders. The building which is of Indiana limestone and tapestry brick has been designed to promote the efficiency and comfort of employees.

Victor Rubber Co., Springfield, Ohio, is booking large orders for future delivery, according to President H. S. Berlin, due to recent price reductions. He states that an increase in production to a normal basis will be made within the next few weeks and that the expectations are that by December the output will reach normal.

Pierce-Arrow Co. reports that orders for parts necessary to complete 250 automobiles have just passed through its production department. This is an increase over the 200 cars produced last month and a large increase over production in the corresponding period a year ago.

Painesville Rubber Products Co. has acquired from the Middle States Rubber Co. of Cleveland the plant at Painesville, Ohio, formerly occupied by the Perfection Tube Co. The new company is incorporated for \$60,000 and will employ between 25 and 50 men.

Milwaukee Auto Engine & Supply Co., Milwaukee, has changed its name to Milwaukee Motor Products, Inc. There has been no change in the personnel or policies of the company.

Franklin shipments from the factory at Syracuse for the quarter ended Sept. 30 were 103 per cent of those for the corresponding period last year.

Advance Automobile Accessories Corp., Chicago, has absorbed the Rochester Woven Belting Corp., of East Rochester, N. Y.

## BUFFALO OPTIMISTIC

BUFFALO, Nov. 9—Regardless of the fact that fewer new cars were sold here during October than in September, and that the outlook is that November's busi-

ness will be slightly less than was October's, Buffalo's automobile dealers take into consideration the fact that October and November are the poorest business months in the year, anyway. They are sanguine that with the approach of the new year the pendulum will swing the other way and that long before the robins return from the southland the selling of automobiles here will be well on the way to normalcy.

## School of Industrial Journalism Is Opened

NEW YORK, Nov. 8—Fifty employees of the Class Journal Co., representing all departments and including a half dozen young women, attended their first lecture in the School of Industrial Journalism which has been established by the publishers of the leading business papers of the country.

The purpose of the course, which will cover 30 weeks, is to make the papers in the industrial field more valuable to their readers by means of a better rounded training for those who get them out. The first lesson was devoted to the fundamentals of business publishing and the lecturer was M. C. Robbins, editor of *The Gas Age*.

## Ford Says Country Is Coming Back to Normal

BUFFALO, Nov. 8—"Business conditions are improving everywhere." This was the statement made by Henry Ford during his stay in this city. Ford and his party arrived here from Green Island, where Ford had been inspecting his new plant. They left the following morning for Detroit in an imported English car. The entire trip was made in this car.

Ford discussed very informally problems of unemployment, unionism, prohibition, politics and the recent threatening railroad strike.

"Unemployment to-day is a problem created by the manufacturers," said Ford. "Many manufacturers who became rich during the war are now too lazy to open their factories."

It was suggested that the manufacturers claim that they have decreased production because the demand has diminished.

"No," replied Ford, "the trouble lies with the manufacturer who is neglecting to sense the public's wants."

"Business is picking up," he continued. "We are coming back to normal. It is difficult to say just what normal is, but the year 1915 might be called normal. In that year wheat was selling for one dollar a bushel. That is what wheat is selling for at this time. We might use this as one indication that we are approaching normal."

## WESTCOTT SHIPS TRAINLOAD

SPRINGFIELD, OHIO, Nov. 8—A trainload of seventy automobiles will leave the plant of the Westcott Motor Car Co. for the Chicago distributor this week. Orders received recently from Belgium are taken as showing the possibility of a revival in export trade.

## BANK CREDITS

Written exclusively for AUTOMOTIVE INDUSTRIES by the Guaranty Trust Co., second largest bank in America.

That the general trend of the money market is downward was hinted at in the interest rates for the recent offering of United States Treasury Certificates of Indebtedness, and was further confirmed during the past week when lower rediscount rates on all classes of paper were announced by all of the Federal Reserve Banks. The action of the New York bank marked the fifth successive reduction since last May.

Although the rates at the twelve institutions vary from  $4\frac{1}{2}$  to  $5\frac{1}{2}$  per cent at each individual bank a uniform rate is set for all classes of paper. Following the announcement of the reduction by the New York bank, the Bank of England on Thursday reduced its rediscount rate from  $5\frac{1}{2}$  per cent to 5 per cent. In spite of these general reductions, there was a tendency toward stiffening in the week's local money market. Call loans ranged from  $4\frac{1}{2}$  per cent to 6 per cent, as compared with 5 per cent to 6 per cent in the previous week, and renewals were negotiated at a ruling rate of  $5\frac{1}{2}$  per cent.

The effect of the lowering of the rediscount rates was perhaps noticeable in time money. Sixty-day maturities were quoted at 5 per cent, those from 90 days up to 5 months at  $5\frac{1}{4}$  per cent, and 6 months maturities at  $5\frac{1}{2}$  per cent to  $5\frac{3}{4}$  per cent, as against  $5\frac{1}{2}$  per cent for 60 and 90 day paper, and  $5\frac{1}{2}$  per cent to  $5\frac{3}{4}$  per cent for longer maturities up to 6 months in the previous week. Prime commercial paper was quoted at 5 per cent to  $5\frac{1}{4}$  per cent, as against  $5\frac{1}{2}$  per cent to  $5\frac{3}{4}$  per cent in the previous week. Although funds seemed to be readily available, the volume of transactions continued light.

The number of commercial failures reported for the month of October was 1713, with total liabilities of \$53,058,659. The number of October failures is the largest of any month this year, and is 790 more than in the month of October, 1920. Liabilities, however, were exceeded in amount in February and March. On Thursday of last week, wheat prices dropped to the lowest point of the year, when the Chicago wheat market reported sales at less than \$1 per bushel. Nearly all of the bonds on the list of high grade, long term securities touched new high levels during the past week, and one Government issue, the  $4\frac{1}{2}$  per cent Victory Loan, touched par for the first time in 1921.

## JAMES L. GEDDES IMPROVING

SPRINGFIELD, OHIO, Nov. 8—Announcement is made that the condition of James L. Geddes, chairman of the board of directors of the Kelly-Springfield Motor Truck Co., who has been in poor health for the past year and who a few days ago was stricken with paralysis, affecting his left side, is improving gradually.

## MEN OF THE INDUSTRY

**Myron E. Forbes**, who has been treasurer of the Pierce-Arrow Motor Car Company since August, 1919, has been made vice-president of the company. He will continue to act as treasurer. Forbes was one of the chief accountants of Haskins & Sells at the time the \$65,000,000 merger was effected by Deere & Co. Soon after he became auditor of Deere & Co., and later was appointed general manager of the Deere plant at Welland. In 1914, Forbes was made secretary and treasurer of the Syracuse Plow Co., a subsidiary of the Deere company.

**F. W. Fenn**, secretary of the motor truck committee of the National Automobile Chamber of Commerce, has been invited to deliver lectures on highway engineering and highway transport engineering in the following universities: He will speak at University of Michigan in February for the third successive year; at Syracuse University in December, at the Massachusetts Institute of Technology in March and at Toronto University on a date which has not been determined.

**C. G. Sinsabaugh**, who is widely known in the industry, has been appointed general manager of *Motor Life* by the new owner of that property. Prior to his becoming associated with *Motor Age* in 1905, an association that lasted ten years, he was connected with daily newspapers in Chicago. From 1915 to 1919 he served with *Motor* in New York and for the last two and one-half years has been with *Motor Life*.

**Frank M. Germane** has resigned as director and sales manager of the Marlin-Rockwell group, effective Dec. 31. He joined the old Standard Roller Bearing Co. in 1903 as western sales manager in Chicago. Two years later he went to the Philadelphia factory as sales manager and became successively general manager and vice-president until the company was absorbed by the Marlin-Rockwell interests.

**J. L. Irving** has been appointed general manager of the Rock Island Plow & Tractor Co., Rock Island, Ill. He became associated with the company twenty-three years ago, and since then served as branch manager, superintendent, assistant general manager and trade manager. He resigned in 1920 to engage with his son in the wholesale and retail tractor and implement business at Los Angeles.

**C. W. Price, W. R. Rasmussen** and **Frank W. Pardee**, long identified with the safety movement, have organized the Price-Rasmussen Corp. to extend consulting and personal service in public safety. Price, who was formerly general manager of the National Safety Council, is president of the corporation. Offices will be in the First National Bank Building, Chicago.

**Paul Kleiber**, president of the Kleiber Motor Truck Co. of San Francisco, was in New York this week looking into the prospect for export business. He is on his way to Atlanta, where his company proposes to erect a branch factory. Kleiber states that retail business on the coast has been satisfactory, although wholesale trade has fallen off heavily.

**John P. Franck**, for the past four years sales manager of the Guide Motor Lamp Mfg. Co., Cleveland, has resigned to become sales manager for the Thos. J. Corcoran Lamp Co. of Cincinnati. Franck is also sales manager for Dittwiler steering gears, Gallon, Ohio, and the Becker Varnish Co., Cincinnati. His offices are in Cleveland.

**A. B. Qualy**, assistant secretary of the Willys Corp. and private secretary to John N. Willys has been transferred to the Willys-Overland plant at Toledo where Willys will spend much of his time in future. The purpose of the move is to have some one stationed in Toledo who is thoroughly familiar with Willys' affairs.

**George A. Richards** has resigned as Detroit district manager for Firestone Tire & Rubber Co. to become manager of a department for Fisher Body Corp. He has been succeeded in the Firestone office by L. R. Jackson, formerly branch and district manager in California and Minneapolis.

**A. Z. Polhamus**, for the last year president of the Visible Pump Co., with offices at Fort Wayne and a plant at New Haven, Ind., has resigned. **S. B. Rohrer**, who for some time has been connected with the company as first vice-president and treasurer, has been elected president.

**H. S. Quick** has been appointed director of sales of the Auto Specialties Mfg. Co., St. Joseph, Mich., and will specialize in promoting sales in the shock absorber and jack division. He was formerly branch manager of the Chicago branch of the Hassler Shock Absorber Co.

**J. J. Wilson**, formerly in charge of the foundries of the General Motors Corp., has become manager of the foundry division of Hiram Walker & Sons Metal Products, Ltd., Walkerville, Ont., a new company which will make a general line of motor castings.

**Daniel G. Head**, formerly associated with the Federal miniature lamp division of the National Lamp Works of General Electric Co., has become sales manager of Culver-Stearns Mfg. Co., Worcester, Mass., manufacturer of automotive electric lighting accessories.

**R. E. Chamberlain** has been promoted to the position of general sales manager of Packard Motor Car Co. He has been connected with the company in other capacities since 1916, being assistant general sales manager for the last year.

**F. A. Morrison** has been appointed assistant secretary of the Maxwell Motor Corp. and assistant secretary of the Chalmers Motor Corp. Morrison has been connected with the Maxwell-Chalmers organization for several years.

**George C. McDonald**, for the past fifteen years identified with the steel castings industry in Detroit, has become associated with the Monroe Steel Castings Co. of Monroe, Mich., in charge of sales.

**William A. Henderson**, manager of the Dort Motor Car Co.'s body plant at Kalamazoo has resigned his position and returned to his former home in New York City.

**Allan A. Macool** has been appointed sales manager of the Flexo Co. of America, Philadelphia, manufacturer of an attachment for the Ford truck.

**W. H. Olmstead** has been appointed sales manager of Carlisle Tire Corp. and will be located at the factory at Stamford, Conn.

## TO SUE ROAD DEPARTMENT

LOUISVILLE, Nov. 7—Members of the Kentucky Motor Club, by a majority vote, have authorized the filing of a suit against the State road department to compel observance of a Court of Appeals decision given in 1917. The suit, if successful, will require that the fund derived from automobile license fees be applied to maintenance of completed highways in the State.

## FINANCIAL NOTES

**R. H. Collins** has made the initial payment of \$1,857,581 which is to be paid at the rate of \$23.33 a share to the stockholders of the Peerless Truck & Motor Corp. who have pledged their stock under an agreement whereby Collins will buy a maximum of 50,000 shares of the stock of the Peerless company at \$50 a share. Under the new purchase plan it is purposed to make payments in four installments over a period of from 18 to 36 months, a payment every six months, interest on the balance being at 6 per cent.

**Goodyear Tire & Rubber Co. of Canada, Ltd.**, reported for the quarter ended Sept. 30 net profits, after all expenses, interest charges, depreciation, etc., of \$200,129. This added to \$100,760, at credit of profit and loss account, brings the total to \$300,889. The balance sheet as of Sept. 30 last shows current assets of \$6,971,830, current liabilities \$1,701,836; inventories \$2,985,137; accounts receivable \$3,116,418; cash on hand \$870,275 and total assets \$14,139,804 against \$15,322,999 on June 30.

**Rickenbacker Motors Co. of Detroit** has been authorized by the Ohio Securities department to place 100,000 shares of common stock on sale in Ohio at a price netting the company 85. The company has an authorized capital of \$5,000,000 divided into 500,000 shares of common stock, par value \$10.

**Moline Plow Co.** reports that under the reorganization plan of Sept. 22, 1921, 92 per cent of the outstanding claims of creditors have been deposited. Time for depositing claims and all classes of stock has been extended to Nov. 21.

**International Motor Truck** showed net profits for the quarter ended Sept. 30 of \$12,634 after taxes and depreciation. For the nine months ended Sept. 30 net profits were \$540,668.

**Stewart-Warner Speedometer Corp.** reports sales and shipments during Oct. 1921 were 48 per cent in excess of October a year ago.

**White Motor Co.** has declared its regular quarterly dividend of \$1 a share, payable Dec. 31 to stock of record Dec. 10.

Kelly-Springfield  
Reduces Obligations

SPRINGFIELD, OHIO, Nov. 9—The Kelly-Springfield Motor Truck Co. reduced its obligations to trade creditors from August, 1920, to Oct. 22, 1921, by \$448,507.80. Its unpaid balance represented by open accounts and notes payable to trade creditors amounted on the latter date to \$211,454.12.

The quick assets of the company aggregate \$3,517,388.92 and the quick liabilities \$1,562,912.51; the excess quick assets are \$1,988,472.47. The liabilities include accounts payable of \$135,767.21 and notes payable of \$1,427,145.30. A large portion of the notes payable consist of notes to banks and bankers.

The company's plant is in operation at this time. Efforts are being directed by the company on the development of special equipment for additional fields in which it is a rapidly increasing demand for its product.

# Calendar

## SHOWS

- Nov. 14-19—Jersey City, Second Annual Automobile Show of Hudson County Automobile Trade Association, Fourth Regiment Armory.
- Nov. 27-Dec. 2—New York, Automobile Salon, Hotel Commodore.
- Jan. 28-Feb. 4—Chicago, Automobile Salon, Hotel Drake.
- Jan. 7-13—New York, National Automobile Show, Madison Central Palace, Auspices of N.A.C.C.
- Jan. 28-Feb. 4—Chicago, National Automobile Show, Coliseum, Auspices of N.A.C.C.
- Feb. 6 to 11—Seventh National Tractor Show and Educational Exposition, Minnesota State Fair Grounds, Minneapolis.
- Feb. 6 to 11—Winnipeg, Can., Automotive Equipment Show, Western Canadian Automotive Association.

- Feb. 20 to 25—Louisville, Ky., Louisville Automobile Show, Auspices Louisville Automobile Dealers Association.

## FOREIGN SHOWS

- Nov. 4-12—London, British Motor Show, Society Motor Mfrs. and Traders.
- Nov. 4-12—Car Show, Nov. 28-Dec. 3—Motorcycle Show.
- Nov. 7-14—Paris, Seventh International Exposition of Aerial Locomotion in the Grand Palais of the Champs Elysees, Held by the Chambre Syndicale des Industries Aeronautiques.
- Nov. 12-27—Buenos Aires, Annual Motor Show, La Pabellon de las Sosas, Automovil Club Argentino.
- Nov. 26—Dec. 3—Shanghai, China, Automobile Show.
- March, 1922—Santiago, Chili, Annual Automobile Show.
- May, 1922—Quito, Ecuador, Agricultural Exposition, celebrating Centenary of Ecuador. Automotive Section.

- Sept. 1922—Rio de Janeiro, Brazil, Automobile exhibits in connection with the Brazilian Centenary Association Automobilista Brasileira.

## CONVENTIONS

- Nov. 14-19—Chicago, Annual Meeting and Business Exhibit of Automotive Equipment Association.
- Nov. 15-16—New York, Convention of Factory Service Managers, National Automobile Chamber of Commerce.
- Nov. 21-23—Atlanta, Third Annual Convention of American Farm Bureau Federation.
- Dec. 6-8—Chicago, Second Annual Meeting of American Petroleum Institute.
- Dec. 10—New York, American Institute of Mining and Metallurgical Engineers.

- Dec. 20—Philadelphia, American Society of Mechanical Engineers.
- Dec. 27-29—Chicago, American Society of Agricultural Engineers, Auditorium Hotel.
- Jan. 17-20, 1922—Chicago, American Road Builders Association.
- Jan. 30-31—Chicago, Fifth Annual Convention, N. A. D. A., La Salle Hotel.
- June 11-15—Milwaukee, Annual International Convention of the Associated Advertising Clubs of the World.
- Sept. 18-23, 1922—Rome, Italy, Second Annual Meeting of the International Chamber of Commerce.
- S. A. E. MEETINGS**
- Detroit, Nov. 18, Dec. 23, Feb. 24, March 24, April 28, May 26.
- New York, Jan. 11-14, 1922—Annual Meeting.
- Chicago, Feb. 1
- Minneapolis, Feb. 8—Tractor Meeting.

## Theft Is Hazardous Under Missouri Law

### Bestor Statute Places Motor Vehicles on Same Basis as Real Estate

ST. LOUIS, Nov. 7—Motor vehicles are placed on much the same basis as real estate and theft of them is made hazardous by the Bestor motor vehicle law, which became effective this month. The law revises all State statutes on motor vehicles and makes laws applied about the same in country as in city.

One of the provisions intended to stop automobile thefts is the requirement that each owner of a car obtain from the commissioner of motor vehicles a certificate of ownership which must be passed with each sale of a car just as a deed passes with a sale of real estate.

No license plates may be issued until such a certificate has been obtained, \$1 paid and all data by which the individual car may be identified, furnished. Every owner of a motor car in the State must obtain a certificate within four months after the law goes into effect.

The certificate is good until the car is sold. Then it must be indorsed with a warranty of title and transferred as a deed. The new owner must present the assigned certificate when he gets his license plates. In case the car is sold out of the State or dismantled, the certificate must be returned to the commissioner of motor vehicles. Sale of a car without transfer of the certificate is declared unlawful, fraudulent and void.

The police may require drivers of cars to establish ownership by production of the requisite certificate, and the commissioner of motor vehicles is required to help trace stolen cars taken into other States.

Dealers must make monthly reports to the commissioner of all cars sold. Gar-

age proprietors must keep a record of cars owners and identification marks on all cars they store. Obliterating or altering a motor number is declared *prima facie* evidence of larceny. Garage owners are required to notify the police of such cases and to hold cars 48 hours.

## Good Highways Bill Signed by Harding

WASHINGTON, Nov. 9—President Harding to-day signed the highway bill, bringing to an end the long fight over good roads. The Bureau of Public Roads will now select the States and roads where the funds will be distributed. In explaining the fundamentals of the law, Senator Townsend, who sponsored the bill, says:

"Before any state can participate in Federal aid it must lay out a system of roads approved by the Secretary of Agriculture, consisting of not more than seven per cent of the road mileage of the state. Three-sevenths of that percentage shall be interstate mileage, connecting with similar roads in adjacent states and four-sevenths inter-county roads, connecting with the inter-state highways.

"Fifty per cent of the state's share of the Federal money will be spent upon interstate roads until they are completed, and, with the consent of the state highway department, all of this money may be spent on these highways."

## NEW NASH SERIES

KENOSHA, Nov. 10—The Nash Motors Co. announce a new series of six-cylinder cars, including five and seven-passenger touring, roadster, coupé, sport model and sedan, to be known as series 691. The major specifications remain the same as for the current model, but several refinements in details have been incorporated. The bodies are characterized as being of the straight line type and are of lower appearance. The spring suspension has been slightly altered to give improved riding qualities. Delco electrical equipment is now employed.

## California Demand Brisk in New Cars

### Improvement Is Also Apparent in Movement of Used Stocks

OAKLAND, Nov. 7—Conditions in the automotive merchandising industry throughout California are improving, though business is slower in some sections than in others, according to Robert W. Martland, secretary-manager of the California Automobile Trade Association, who has just completed a trip of several thousand miles through California, in which he held meetings of bankers, business men and automobile dealers in more than 50 cities and towns. He said:

"Motor car dealers report the demand for new cars brisk, and that used cars are moving faster now than they were a few months ago. Many of the dealers are taking serious losses, however, in order to clean up their stocks of used cars and square away for winter and spring business. Eastern motorists, dealers and repairmen whom I have met in various parts of the state were surprised at the excellent conditions prevailing in the automotive industry in California.

"Comparatively speaking, California is prosperous and the automobile dealers are more than 'breaking even.' Here, in the San Francisco section, members of the association are reporting a gradually increasing demand for cars and all expect an improvement in business during the winter.

"With nearly half a million passenger automobiles in operation in California, it is small wonder that the members of our association, who do most of the repair work, are going ahead. I find that the men who are dealing fairly with the public, setting their prices low enough to stay above board, and still are doing good work, are getting the business. Price-cutters are having a hard time of it, because the cost of standard articles has been reduced to such an extent that the public would rather buy a good article at a low price than pay a little less for an inferior article."

*The* AUTOMOBILE

Vol. XLV  
Number 20

PUBLISHED WEEKLY AT 239 WEST 39th STREET  
NEW YORK, NOVEMBER 17, 1921

Thirty-five cents a copy  
Three dollars a year

Conservación de fuerza es uno de los rasgos característicos en cuanto a utilidad de las Chumaceras Cónicas de Rodillos Timken. Ellas evitan grande y frecuente lubricación y, debido a su propio diseño, las ensambladuras de chumaceras resultan más livianas y compactas.

Conservation of power is but one phase of the utility of Timken Tapered Roller Bearings. They eliminate the frequent lubrication bug-bear, and by their very design make possible lighter and more compact bearing assemblies.

## *Another Reason for Concentration in Buying*

The expenditure of vast sums of money for surplus stocks is inevitable today in the successful manufacture of motor cars.

Many executives, however, have greatly decreased such expenditure through concentrating their purchases in one source of supply.

One item of expense that may be materially lessened through centered buying is the purchasing of automobile body hardware *exclusively* from Ternstedt.

Ternstedt Equipment is delivered to your door just as you require it. All units, being of standard design, you have waiting at the Ternstedt plant an immense reserve, instantly ready at your call. There is apparatus for every possible need.

As you pay for Ternstedt Hardware only as you receive it, capital, ordinarily invested in heavy surplus stocks, is released for other purposes. The saving is quickly apparent.

Those who have become familiar with this and the many other advantages of concentrating in Ternstedt are specifying Ternstedt Hardware *exclusively*. The list is large and rapidly growing.

## Statistics for Use in Making Sales Plans

Here is statistical data never before available. More detailed material will follow. This article discusses the use of such information and general trends in the passenger car field. Industry shown to be on sound basis for future progress.

By Norman G. Shidle

**T**HE marketing problem of the automotive manufacturer divides itself in a general way into two parts and in working out that problem studies are likely to follow two general lines. The first of these consists of the principles of marketing which underlie all sound procedure. In this field might be included all those studies designed to lay out the various factors involved in automotive marketing, to determine the relation between these various factors, human, statistical and economic, the unit cost of marketing, and the other fundamentals upon which rests the development of effective practice and performance.

These form a basis, and current marketing discussions in AUTOMOTIVE INDUSTRIES are designed to contribute constructive thought along these lines. In addition to such fundamental studies, however, another phase of marketing must be considered which includes the assembling and proper interpretation of actual facts as regards the industry and its marketing possibilities. This includes the development of accurate statistical data, compiled to aid in the solution of definite selling problems.

Such accurate data is extremely difficult to obtain concerning the automotive industry, as has been

pointed out before, yet once compiled and properly utilized by individual firms within the industry it might materially reduce marketing costs and greatly aid the return to a strong economic position.

In connection with statistical data concerning the automotive industry then, there are two major requisites:

1. Statistical data must be accurate.
2. It must be sanely interpreted, due emphasis being given to factors affecting the situation which cannot be reduced to statistical form.

These requisites cannot be fulfilled except through very extensive and careful research and through an intelligent and analytical consideration of the results of such research.

Such data as regards certain phases of the automobile industry, AUTOMOTIVE INDUSTRIES is able to present for the first time.

For marketing purposes it is essential that all material be presented in segregated form, since the marketing of each kind of automotive vehicle constitutes a problem in itself. General data concerning a given type of vehicle will enable the manufacturer to visualize the present condition and future possibilities of the industry as a whole and to discuss intelligent-

ly what is likely to happen during the next few years.

With this general picture as a background he will want more detailed data concerning the developments within his particular price class, in given sections of the country, etc. Upon the basis of these more detailed statistics he will be able to analyze the market for his own particular product more accurately and to direct his sales effort more efficiently.

Within the scope of a single article only one of these phases can be adequately discussed. The charts presented here are designed to show what may reasonably be expected in passenger car sales, production and registration during the next two to five years. The information presented by the charts is valuable because of the accuracy of the figures used and because of the soundness of the basis upon which the moderate predictions are made.

It is important that the basis upon which the figures were compiled and the charts drawn be thoroughly understood before any attempt to interpret the results is made. This is true because no intelligent interpretation of any set of figures or charts can be expected unless the details of the statistical work are understood.

All interpretations of statistical work are not sufficiently concerned with this phase, and as a result statistical data of some relative value has been misinterpreted in the past. Considerable harm can accrue both to an industry and to an individual marketing plan through a hasty interpretation of statistical results which fails to consider the factors involved in the statistical work.

The charts presented here have to do specially with the passenger car part of the automotive industry. The first chart shows passenger car production figures, and the second chart passenger car registration figures. The first is merely a general progress curve designed to show the trend of any industry over the three periods of its development.

Mr. Prescott's explanation of the bases upon which these results were built up follows:

The growth of population of all countries as well as their economic activities, i.e. farming and industry, all extractive industry excepted, seem to follow a defined growth which passes through four stages in the course of its progress. These four stages are: period of experimentation, period of growth into social fabric, through point of "Diminishing Returns," into period of stability. Knowing the fundamental curve of growth that industry seems to follow with uncanny accuracy, it is not difficult to conceive that when one part of that growth is known the other can be forecast. To explain past performance and predict the future are not different operations. They are the same operation but working in opposite directions, one from effect to cause and the other from cause to effect.

During the period of experimentation, the permanent success of an industry is doubtful, because man is a creature of habit. It is difficult to change him from the

groove in which he is traveling. He accepts very slowly anything that tends to change his routine. The success of this industry depends upon how well the opposition habits of man are overcome.

If the industry successfully overcomes this opposition it enters the next period of growth into social fabric; if not, it fails. In this period the development of the industry is slow or rapid, depending upon how well the opposition is overcome. Sooner or later, if successful, the industry will pass through point of "Diminishing Returns," that is where its growth increases but at a diminishing rate.

It then enters the period of stability where it adjusts itself and becomes a part of the social and economic life of that country. To study and measure the growth of various economic activities, it is necessary to have a clear conception of what constitutes and influences this growth.

Every industry is comprised of many individuals that produce, distribute and use the product, varying from small industries having only a few to large industries with national distribution having several million.

All these individuals exert some influence on the growth of the industry. Some of these influences are favorable or plus, while some are unfavorable or minus. It is the summation of these individual plus and minus influences that determines the progress of the industry. The influences may be grouped as internal and external. The internal may be controlled to a large extent, but the favorable external factors have to be created by strong internal influences. Internal favorable influences are comprised of capable executives that build up strong organizations for

producing and marketing the product, which are reflected externally in policy, good will and competition. These influences are measured in the volume of business, whether it is units of production or value of product. This history or progress may be shown graphically by the curve in Fig. 3 that seems to be fundamental for all industries that are a direct or indirect function of population. As every industry has many different influences, so every industry will have a different rate of growth, but the trace of the curve will be the same.

As the record of past performances is the history of that industry, it is necessary to have these records accurate and as complete as possible, in order that accurate results can be obtained from the use of the equation designed to measure the past and predict the future of industries. This equation, used in constructing the accompanying charts, was tested on cotton, railroads and pig iron. It forecast in the case of cotton the probable production of cotton thirty years in advance with an error of 2 per cent; in the case of railroads twenty years in advance with an error of 3 per cent; and in the case of pig iron, ten years in advance with 3 per cent error. All of these activities can furnish accurate data for a long period. It is hardly to be expected that the data of the automobile industry, which is for a very short period and of a very uncertain nature, can be fore-

---

**C**ONSIDERABLE space has been given here to an explanation of the basis and compilation of the statistics upon which the conclusions have been drawn. This explanation is important, since it forms a basis, not only for the material presented here, but also for future marketing statistics which will appear in coming issues. Conclusions drawn from statistical data are valuable only in so far as the basis of the data is understood, and the limitations as well as the value of the material considered.

Accurate statistics concerning certain phases of the automotive industry are not yet available. But accurate material concerning many phases has been developed by Raymond B. Prescott of AUTOMOTIVE INDUSTRIES Research Staff as a result of many years' careful study, analysis, and investigation and can now be given to the industry.

---

Fig. 1

Fig. 2

cast as accurately as the above. But the absence of accurate data over a long period does not preclude the use of mathematical analysis as a tool in anticipating the future trend.

The equation that has been fitted to the data mentioned above, with the results given, is as follows:

$$(1) y = ab^{c^x}$$

$$(2) Y = A + c^x B$$

Let now  $x$  become successively  $x_1, x_1 + 1 + \dots + x_1 + n - 1$ . Then taking the sums we get

$$(3) \sum_{x=x_1}^{x_1+n-1} Y = nA (c^x + c^{x+1} + \dots + c^{x+n-1}) B$$

The series of  $c$  is in geometrical progression. Such a series is

$$\begin{aligned} S &= \alpha + \alpha\beta + \alpha\beta^2 + \dots + \alpha\beta^{n-1} \\ \therefore \beta S &= \alpha\beta + \alpha\beta^2 + \dots + \alpha\beta^{n-1} + \alpha\beta^n \\ \therefore S(1-\beta) &= \alpha(1-\beta^n) \text{ and} \\ S &= \alpha \frac{(1-\beta^n)}{(1-\beta)} \end{aligned}$$

Consequently the sum of the  $c$  series is

$$S = c^x \frac{(1-c^n)}{1-c} = c^x \frac{(c^n-1)}{(c-1)}$$

and we may write (3)

$$(4) \sum_{x=x_1}^{x_1+n-1} Y = A + c^x \frac{(c^n-1)}{(c-1)} B$$

This equation (4) will enable us to find the constants in the formula.

There are three constants in the equation, and we therefore need to have three simultaneous equations. If we divide up our observations into three equal parts we have, using equation

$$(4) \sum_{x=x_1}^{x_1+n-1} Y = nA + c^x \frac{(c^n-1)}{(c-1)} B$$

$$(5) \sum_{x=x_1+n}^{x_1+2n-1} Y = nA + c^{x+n} \frac{(c^n-1)}{(c-1)} B$$

$$\sum_{x=x_1+2n}^{x_1+3n-1} Y = nA + c^{x+2n} \frac{(c^n-1)}{(c-1)} B$$

Differencing both sides of these equations, we get

$$\sum_{x=x_1+2n}^{x_1+3n-1} Y - \sum_{x=x_1+n}^{x_1+2n-1} Y = c^{x+n} \frac{(c^n-1)^2}{(c-1)} B$$

$$\sum_{x=x_1+n}^{x_1+2n-1} Y - \sum_{x=x_1}^{x_1+n-1} Y = c^x \frac{(c^n-1)^2}{(c-1)} B$$

These two equations may be written

$$(6) \begin{aligned} \Delta \sum_{x=x_1+n}^{x_1+2n-1} Y &= c^{x+n} \frac{(c^n-1)^2}{(c-1)} B \\ \Delta \sum_{x=x_1}^{x_1+n-1} Y &= c^x \frac{(c^n-1)^2}{(c-1)} B \end{aligned}$$

Now dividing both sides of the first equations in (6) by the corresponding side of the second equations in (6) we get

$$\frac{\Delta \sum_{x=x_1+n}^{x_1+2n-1} Y}{\Delta \sum_{x=x_1}^{x_1+n-1} Y} = c^n$$

Take the logarithms of both sides

$$(7) \log \Delta \sum_{x=x_1+n}^{x_1+2n-1} Y - \log \Delta \sum_{x=x_1}^{x_1+n-1} Y = n \log c$$

Equation (7) enables us to compute at once the value of  $c$ . We may then find  $(b)$  from either of the equations in (6). Finally  $A$  may be obtained from (2).

Note.—As far as the writer has been able to learn this equation has never been fitted to economic data before.

The above equation is a method or tool of forecasting and it is not put forward as a "Cure All," but is simply an improved method over the present unscientific ones used to-day. The equation will not forecast abnormal economic or social eruptions any more than any business executive can predict fires, strikes or destructions of his plant by the elements, but it seems to predict with uncanny accuracy the Law of Growth of industries that are a direct or indirect function of population. Marshall ably said: "History tells of sequences and coincidence, but reason alone can interpret and draw lessons from them." This equation as fitted to data of the automotive industry should make it far less difficult for the executive having intimate knowledge of that particular activity to shape his policies several years in advance with a high degree of accuracy.

The data used to fit the equation has been carefully computed from confidential figures collected after years of close association with the industry. It is as nearly correct as it is humanly possible to obtain at the present time.

The registration figures for passenger cars have been obtained from an actual count of registration records of the various states. Even this method involves slight inaccuracies under present registration conditions, but the factor of error is less than 1 per cent so that the figures can properly be used for purposes such as this.

This is not true as regards truck figures, however, at the present time. This may be explained as follows: Those states which do not segregate in any way cars and trucks—and there are still about 15—list the name of the vehicle without designating its type. In the case of those firms which make both cars and trucks, it is impossible to determine, even from an actual count on the records, the exact division.

Consequently, the passenger car figures include those trucks in the states where there is no segregation which are made by concerns manufacturing both cars and trucks. But these trucks are so small a percentage of the total passenger car registration that they do not affect the resulting figures.

The only truck figures available, on the other hand, include merely those trucks made by companies which manufacture only trucks. These figures would not include those trucks made by companies which also manufacture passenger cars. In this case the trucks made by companies which also make cars form so large a percentage of the total truck registration as to affect the results very materially. Hence, truck studies similar to the passenger car studies presented, are not possible at the present time.

The figures are not available from any total registration figures that are now published, since they are subject to many errors owing to the many methods of classifying motor vehicles in the states.

This explanation indicates that these charts have been built up on a fundamentally sound basis, and that they can be relied upon as picturing accurately the probable development of the passenger car industry during the next three to five years. It is not claimed that the figures are exact to the last degree. The figures themselves, however, and the basis upon which they have been compiled are sufficiently accurate to reduce the possible error to one or two per cent for the period covered, provided no unusually abnormal factor, such as the war, enters.

With this thought in mind, it is possible to intelligently study the charts and the results which they give.

It is recognized everywhere, of course, that every industry in the country was given an abnormal impetus by the

demands of the war. Production capacities in all industries increased as much during the years of this abnormal condition as they normally would have done in twice or three times as long under normal conditions. Thus, to say that the automobile industry has piled up a production capacity in excess of its immediate needs, is merely to state an obvious fact that is true of every other industry.

A close analysis of the charts, however, indicates that the passenger car industry, despite the rapid increase during the war period, has not taken nearly so great a deviation from normal as have many other similar industries.

Assuming for the purposes of discussion that "normal" may be defined as a period in which the industry is producing at a rate equal to the highest production point it has yet reached. On this basis, it appears that it will take two years for the passenger car industry to return to "normal."

The highest production reached by the passenger car manufacturers was slightly under 2,000,000 in 1920. This is less than 500,000 over what the normal production would have been for 1921, had there been no artificial acceleration due to the war. It is about 200,000 more than the normal for 1922 would have been.

And it is just the same as the normal for 1923.

That is, if the industry is not interrupted by any abnormal disturbances during the next two years, it will be back to normal by 1923. This is a decidedly encouraging outlook, since the definition of normal used in this discussion means that practically every passenger car plant in the industry will be going full blast, provided the production capacity remains at its present level. This proves the automobile industry to be in a favorable, rather than an unfavorable, position as compared with many other industries which may properly be compared with it. It refutes the prophets who have seen catastrophe ahead for the automobile industry.

This optimism is particularly sane, when it is realized that it is not necessary for every plant in the industry to be producing at 1920 capacity rate in order that there be a good profit available. Producing at the rate shown to be possible by this curve, it appears that there is an excellent business available during 1921 and 1922, even though 100 per cent production is not warranted during that time.

It is evident that the measure of soundness and prosperity of the industry is in direct proportion to the distance between the normal trend line and the actual production or sales line. This distance was less in 1920 than it was in 1917. Fundamentally the passenger car industry is more sound and on a better basis than it was during the boom period of 1917, and is rapidly returning to normal.

The registration curve shown in Fig. 2 is of special interest since it shows how closely the actual registrations in the past have coincided with the predictions of this normal trend curve. This appears to be true in spite of the abnormal conditions caused by the war and the present business depression. The variation between the normal and the actual in this curve is less than in the production curve partly because the numbers involved in the calculation are considerably larger, thus reducing the percentage of error. For this same reason, the deductions of this curve may be accepted as accurate some years further in the future.

This chart shows that in 1923, the year in which the in-

dustry is scheduled to be back to normal, the registration will be in the neighborhood of 17,000,000 passenger cars. The registration predicted by this normal curve for 1921 is about 8,700,000 passenger cars. It will be interesting to observe how close to this predicted figure are the passenger car registrations for 1921.

It is obvious that the per cent of increase in registration must become less very soon, yet the curve shows that there will be a material increase in actual registration for some years to come, and that the much talked of saturation point is not yet visible. In making the interpretation, attention should again be directed to the basis upon which the normal curve has been constructed, since it is only the soundness of that basis that renders the information valuable.

It is interesting to compare the variation from normal which the war gave to the automobile industry with similar effects in similar industries. The best available figures, for instance, as regards the talking machine industry indicate that its abnormal expansion or variation from normal is very materially greater than that of the automobile industry. This is found to be the case in numerous other instances. A survey of comparable industries, in fact, indicates that the position of the automobile industry, as regards getting back to normal, is better than many others.

There may be some objection to the conclusions drawn here on the basis that the highest production capacity reached by the passenger car industry is not identical with the production capacity of the industry. This is a theoretical rather than a practical criticism, since the passenger car industry from a business point of view was considered throughout the country to be working at "capacity" during the year its peak production was reached.

Production capacity, in any case, is difficult to define in a theoretical sense. It cannot properly be said to include buildings owned by manufacturers which have never been equipped for actual production, but have simply been acquired for purposes of future expansion or development.

To refer again to the curve of passenger car registrations shown in Fig. 2, it is interesting to note how closely the normal trend curve coincides with the actual registration curve, in spite of the abnormal business conditions which have prevailed during recent years. While it becomes apparent that the rate of increase of registration during the next ten years will be considerably less than during the previous ten years, it is evident also that there will be a definite increase nevertheless.

Not only will production facilities be needed to take care of that development, but also service must be improved and developed, thus broadening the wide scope of business growth that may be expected in the automotive industry during the next decade. The industry is entering upon its period of stability. The automobile has become a fixed unit in the life of the people.

The automobile industry thus appears to be on a sound basis. It is rapidly returning to normal, gives evidence of an excellent market in the immediate as well as in the more remote future, and has an opportunity to do an excellent business, profitable to the vast majority of firms, during the two years which will be needed to return to normal.

Fig. 3

# Closed Body Production Costs Minimized in Essex Coach

Use of straight-cut lumber, two doors and felt window runners assist in making it possible to produce a five-passenger closed car to sell at only \$300 more than open body on the same chassis.

By J. Edward Schipper

**T**HE new Essex Coach, which is to sell at the unusually low price of \$1,495, has just been put in production. It incorporates a number of economy features in closed body construction. The price, which is \$500 below that of the sedan and but \$300 more than the touring car, indicates that something has been done to cut the cost on this body, and a large part of the secret lies in the practical elimination of curved pieces of wood. Substantially all pieces of wood in the body framing are cut on straight lines. This not only materially reduces the cost in preparing the wood framing for assembly, but also, in a number of instances, has resulted in making the assembly work much easier and far more readily handled on an interchangeable basis. An additional saving has been made in the use of two in place

of four doors. This has been made possible by the adoption of individual Pullman-type seats in front in place of the usual fixed type. These seats fold out of the way to allow access to the rear seat. The car is a five-passenger design. The rear seat is continuous across the body in the usual way.

The usual window runners have been eliminated and in their place the felt liners which are old in coach work, have been employed. The glass operates between two fixed lining strips of felt. These not only assist in supporting the glass, but also serve to prevent rattling. The window regulators are of the Dura skew gear type with a worm for the actual lifting of the windows. The crank operates the worm through the medium of the skew gears.

Some steps in the body assembly department at the Essex plant, showing framing for Essex Coach body, note practical elimination of all but straight pieces. The framing for roof is unusually simple. The lower body panels are covered with pressed steel on weather exposed surfaces

The type of body construction employed is such that it is possible to put it together in a number of sub-assemblies. The body may truly be said to be assembled instead of built up in the usual way. There is no great amount of tacking to be done from the inside of the body. This can practically be all done before the body is put together. The roof furnishes a good example of this method of construction. The entire roof is practically a sub-assembly. It is a soft type covered with artificial leather. The actual ceiling of the car, or, as it known, the roof lining, is stretched across the top of the body before the roof proper is put on. This permits of tight fitting and does away with a good part of the usual interior tacking and trimming work. The roof is then put on over the top of this lining as an independent assembly.

Additional economy has been secured by making as many parts on the body of the same dimensions as possible. For instance, all four window frames are of the same size. This also means that the four pieces of glass for the side windows are identical and, consequently, there is no fitting of left and right in putting the body together.

All of the plaited upholstery is detachable. The upholstery is a wool cloth with plaited back and seat cushions in the rear seat.

A sales executive of the Essex company states in exhibiting the coach:

New Essex coach seating five passengers which sells for \$1,495

"The idea behind this car has been to produce a good quality job without going to expense to carry out some of the details in coach work which are more the results of precedent than of necessity or even ornamentation. For instance, instead of going to considerable trouble and expense to cover the heads of the screws, all of the screw heads are exposed. While the manufacturer of an expensive custom body would not tolerate this type of construction, it can be stated that it is far from displeasing to the eye and certainly results in considerable saving in manufacture, which, of course, is what has been aimed at in this body, in which an attempt has been made to provide a closed body at open body figures. The finish has not been slighted as there are twenty-five paint operations, this being fully up to the normal number."

## Cooperation Between the Sales and Accounting Departments

**T**HE gradual return of good business is calling more and more for close cooperation between all the departments of an industrial or business organization. The present time is a splendid one to harmonize effort and every man in industry should be called upon to give his business associate the best he has, and ask from him in return, his best.

These facts, along with many others, were brought out in a paper presented by S. B. Taylor, General Sales Manager of the S.K.F. Industries, before the national conference of the Industrial Cost Association recently held in Pittsburgh. The title of Mr. Taylor's paper was, "What the Sales Manager Should Have from the Accounting Department."

Actual working contact between the accounting and sales departments starts with costs. Cost figures are of prime importance in merchandising and should always be made available. Current information should also be supplied on "In Process" material, including the quantities involved, as well as the stage of manufacturing process.

Certain data giving pictures of sales results should also be made available to the sales department, and Mr. Taylor outlined some of these as follows:

A daily memorandum showing the number and value of orders received, together with the number of units covered, and from what plants ordered; a similar memorandum detailed by customers, with quantities and type of purchase; a weekly report giving all sales, all returns and allowances for the period and to date, the status of unfilled orders and the value of new business accepted, and a monthly report showing the gross profits for the month

with comparisons for the same period of the preceding year.

The proper allocation, through coding, of sales by territory and by industry—assuming distribution to be varied—is an important responsibility of the comptroller's department. Correctly done, it forms a record from which the sales executive may learn much as to the ability of fields to absorb product and the desirability of such a field from the standpoint of profit, to note improvement or retardation as it occurs, also to judge more fairly if various territories, in which there is a common field for sales, are bearing their respective part of the burden.

There were other items which Mr. Taylor said he believed could be used advantageously by the sales department, but he pointed out that different conditions of business called for different plans of operation. The outstanding feature of such practice, however, is to establish a closer relationship between the two departments, and through cooperation develop more sales.

**A** SECOND edition of the *Aircraft Handbook* by Fred H. and Henry F. Colvin has recently been published. The new edition contains considerable new material, while much of the old text has been revised. The book is designed to aid mechanics in becoming familiar with the various phases of aircraft construction and repair. It begins with a general discussion of airplane theory and construction, and goes on to discuss in detail the best known motors. Space is also given to air laws, landing fields, S. A. E. airplane standards and nomenclature. The volume is published by the McGraw-Hill Book Company.

# Engineering Features of British Truck Models

New designs include both light and heavy trucks and a chassis built for omnibus work is a feature of the Dennis factory's products. In Maudslay 6-ton model, the driver's seat is alongside instead of over engine. This article includes descriptions of the new models of seven manufacturers.

By M. W. Bourdon

**M**ANY British manufacturers of trucks exhibited new models at the recent Olympia show, and while there were not many radical departures from custom in their design, various changes which the manufacturers believed will work for the better were noticed. At least one manufacturer of passenger cars has entered the truck field.

One of the new models shown was the new 6-ton\* Maudslay, which has a bigger area of load platform than any other British truck, and is of what has become known as the over-type, though it has the driver's seat alongside instead of over the engine. The steering wheels and controls are on the right, and there is a helper's seat on the left of the engine bonnet. Behind the driver's seat the load platform extends for 19 ft. 6 in.—this on a wheel-base of 14 ft. 6 in.

This new model has a straight channel section (6 x 2½ in.) rolled steel frame with the open side of the channel outward, the overhang beyond the rear axle being approximately 9 ft. In addition to rolled steel cross members at both ends, there are five tubular intermediate cross members, four being of 3-in. diameter and the other of 2½-in. The radiator is at the extreme front end of the frame, and close up behind it is the four-cylinder 4¾ x 6 in. engine which has overhead valve and camshaft, block-cast cylinders and a detachable head.

Maudslay's have always had an overhead camshaft, but in the means of operating it, in the arrangement of the valves, and in having a detachable head and block cylinders there are divergencies from past practice. The inlet valves are seated in cages, but the exhausts have their seats directly in the cylinder head, being removed if necessary through the inlet ports.

The overhead camshaft is driven from the rear end of the crankshaft by bevel gearing, the crankshaft pinion being secured by the same bolts and flange as the flywheel. Half way up the vertical shaft is bevel gearing driving a transverse shaft for the water pump on the left and the magneto on the right, the latter when the body is in position coming under the floorboards of the driver's seat. The pinion at the top of the vertical shaft is driven through a dog clutch, this arrangement allowing the camshaft with its bearing brackets to be lifted out after the holding down bolts have been removed. The camshaft operates the valves through tappets.

The aluminum induction manifold on the right of the cylinders has a very large water jacket. A Zenith carbureter is standard. Aluminum is also used for the two-part crankcase, in the upper half of which the crankshaft has three bearings. Four-bolt big ends are used,

as are hour-glass, cupped head pistons with three rings. Engine and gearset are separately mounted in a four-point suspended sub-frame. The main frame is only 36 in. wide and has the steering gear-box bolted to the extreme front end on the right, with the drag link running back to the swivel arm. The shaft of the clutch, brake and throttle pedals is carried by a single bracket projecting from the outside of the frame just in the rear of the steering box; slightly further to the rear, on the inside of the frame, are the gear lever gate and hand brake quadrant.

A cone clutch is used, whence a coupling shaft some 42 in. in length runs back to the gearset with an internal and external pinion type of semi-flexible joint at each end. Four speeds are provided with ball bearings for all shafts, and a plain bush for the pilot. The open propeller shaft has a star joint at the front and pot (sliding block) joint behind.

Double reduction gearing forms the final drive, the main axle unit being a horizontally arranged double banjo forging, with an aluminum sump and the whole of the gearing carried by an aluminum top section with a pilot extension the full length of the forging ring. The side extensions of the latter are of square section and have the spring and brake shoe brackets clipped on. Straight roller bearings with ball thrusts are used throughout the axles and wheels. Central vertical steering pivots are used, a point of design which was found in one Maudslay model before the war, but was dropped for a time. To secure this feature the hollow stub axle is belled out to 7½ in. diameter at the inner end, to accommodate the end of the beam axle and the swivel pin; this necessitates a very large hub and an inner roller bearing of 10 in. outer diameter—an expensive job, but resulting in easy steering. Brakes consist of a shoe type behind the gearset and expanding shoes in the rear wheel drums 24 in. in diameter and 4 in. wide on their friction surfaces, the shoes being cam-operated. The chassis is priced at £1,275.

The 3 (long) ton Maudslay is also a new model, but only so in respect of the driver's position, who is now also placed alongside the engine on the right. In its general lines the 3-tonner resembles the other, but the overhead camshaft drive is somewhat different. The vertical shaft is *in front* and is driven by helical gearing at top and bottom; the magneto is alongside the crankcase on the right and the pump is driven by belt from the front end of the crankcase. The pump has a distinctly unusual position, for it is bolted to the left-hand corner of the radiator, extending rearwardly. This engine has a bore and stroke of 4½ x 5 in. and the chassis sells at £1,000.

Hitherto the maker of the Guy truck has specialized on a 2½-3 ton chassis, but he has now introduced two

\*All tons referred to in this article are long tons of 2240 pounds, in accordance with prevailing English truck rating practice.

Front end of Maudslay 6 ton semi overttype truck.  
Note gasoline tank alongside frame

Engine and controls of new Maudslay truck. Engine has overhead camshaft, detachable head and block cast cylinders

new models, one of which is for 4500 lb. loads and has the same engine as the original type except that thermosyphon circulation is used. Gear-box, axles and other main parts are the same, but the frame and springs are shorter and lighter.

The other new model is an entirely fresh design and is a type which British makers have hitherto neglected, viz., a 1¼-ton chassis for fast delivery work. This chassis attracted an immense amount of interest among dealers and potential purchasers alike, not only by reason of its engineering features and general design, but also on account of its low price, viz., £395. This compares favorably with the prices of most American truck chassis of similar capacity sold in England. It is an exceedingly well finished job.

The 3¼ x 4½ in. four-cylinder block-cast engine is assembled as a unit with clutch pitch and gearset. The aluminum two-part crankcase is suspended from the main frame by two arms approximately midway of its length, while at the rear of the gearset the unit is slung in two trunnion bearings in a swinging bracket depending from a tubular cross member. The valve arrangement is on the lines of the larger engine described in detail in *AUTOMOTIVE INDUSTRIES* of Oct. 2, 1919.

The detachable cylinder head is inclined from the horizontal to afford a better shape of combustion chamber than would otherwise be feasible. Water is circulated by thermosyphon and a gilled vertical tube radiator with aluminum top and bottom tanks is used, secured rigidly by studs and nuts to the front cross member of the frame.

Trough lubrication is adopted, the gear type pump being at the front end of the camshaft, forward of the distribution casing, and is formed as a unit with a large and accessible strainer. Three plain journal bearings support the crankshaft, the distribution gearing at the front consisting of straight toothed pinions.

To the back of the crankcase is bolted the aluminum bell housing open at the top and enclosing flywheel and dry single plate clutch, the transmission casing being bolted up to it at the rear. Three speeds are provided, with a central lever working in a ball socket. An open propeller shaft is used with a star joint at the front enclosed within a rear extension of the transmission casing; at the rear is a sliding block joint.

Final drive is by top worm gearing, carried as a unit

in an aluminum top cover of the axle casing. The latter is a steel forging with integral sump and has the spring and brake brackets keyed and shrunk on to the integral extensions which carry the wheels on floating bushes.

Both brake lever and pedal operate shoes within the rear wheel drums, the latter measuring 18 x 2½ in. Each shoe forms a segment of approximately 90 deg. and pedal and lever apply alternate shoes.

Either pneumatic or solid tires are furnished, the former at an extra charge of £20; with pneumatics, disk wheels are used; with solids, the hollow cast spoked variety. Steering is by worm and wheel, with magneto ignition control over the hand wheel; the throttle is controlled by pedal only.

The frame is of pressed channel steel, both side members being straight throughout. Springs are half-elliptic and an oil cup system of lubrication is used for the spring pins and other chassis details. Following are some leading particulars: Weight of chassis, 3800 lb.; overall length, 14 ft.; wheelbase, 112 in.; track, 56 in.; dashboard to end of frame, 141 in.; height of top of frame from ground, 28½ in.; gross load capacity, 4000 lb.; direct gear ratio, 6 to 1.

In general this is a good production job, though exception must be made in regard to the valve operation and cylinder head arrangement. These provide selling points no doubt—viz., greater efficiency and accessibility—but whether the additional cost as compared with the normal L head is justified is doubtful. So far as the substitution of rockers for vertical tappets is concerned, there is not much amiss with this from a production standpoint; where the design falls short in the latter respect is in departing from the horizontal and vertical in regard to various machining operations. The top facing of the cylinder block, for example, is set at one angle, the valve guides and seats are at another, while there are, of course, also the vertical cylinder bores and the base flange at right angles to them. These variations from normal can hardly make for a minimum of cost, though taken by themselves they need not, admittedly, account for very much difference; and apparently the makers consider they justify themselves when they are handed on to the sales department. The detachable head cylinders separate from the top half of the crankcase may also fail to secure approval from the production expert.

(Upper left)—T head engine of new Dennis chassis. Note peculiar circuit of water from pump. (Upper right)—Leyland 3 ton full overtype truck with 102 in. wheelbase. Has 64 in. track at front and 52 in. at rear. (Lower left)—Front end of Caledon semi overtype truck chassis with singledeck bus body. (Lower right)—Single sleeve engine of Caledon truck for 15,000 lb. loads. Driver's position is alongside engine

The Dennis truck is one of the oldest among British commercial cars and was the first to adopt worm drive, some eighteen years ago. A 2-ton model was introduced at the 1920 Olympia Truck Show, and this year a new 4-tonner (9000 lb. load) has appeared. While it is suitable for goods carrying bodies, it is primarily intended for omnibus and motor coach work, for with a length of 20 ft. 3 in. from dash to rear end of frame and 15 ft. 4 in. wheelbase, it will take a 56-seated double-deck bus body, or a 36-passenger single-decker. This, however, necessitates an overhang behind the rear axle of 90 in., for no attempt has been made to adopt the forward position for the driver. It is also offered for the carrying of bulky goods.

The pressed steel frame has channels 8 in. deep between the springs and 6 in. at the ends. There are five pressed steel cross members. A long sub-frame for engine and separate gearset is suspended at three points, from a central longitudinal trunnion at the front and by two brackets depending from a main frame and cross-member behind the gearset. The engine rests at four points on this sub-frame, while the gearset is hung below it by two bolts at each of its four corners.

In this new model Dennis retains the pair-cast T head engine design, with integral head  $4\frac{7}{8} \times 5\frac{7}{8}$  in. cylinder on a two-part aluminum crankcase. The crankshaft has three bearings and the connecting rod big-ends have four bolts each. Lubrication is on the trough and pressure system and ignition is by magneto. The pump water circulation is unusually arranged; from the pump on the right of the crankcase the water is delivered to near the top of the front pair of cylinders; passing through the latter it runs back through a coupling pipe to the rear pair, then out at the back and by a single rising pipe to the top of the radiator. This arrangement can hardly be conducive to equal cooling of all the cylinders.

A cone clutch and coupling shaft with two flexible disk joints carry the drive to the four-speed gearset. The latter has a one-piece aluminum box-like casing with an over-all cover plate. All shafts have ball bearings, the main shaft being splined. A shoe type transmission brake is located behind the gearset and a solid coupling shaft 42 in. long  $\times 1\frac{1}{4}$  in. diameter leads to the star universal at the head of the propeller shaft. The latter is enclosed in a torque tube of 5 in. diameter with flanged ends, the

whole machined from the solid bar; the front flange is bolted to a hollow spherical end which encloses the star universal joint and is supported by a cast steel cross-member, itself carried in rubber bushed trunnion brackets on the main frame—the rubber bushes or rings being obviously intended to take up the peak of transmission shocks. Dennis, by the way, has always made a feature of some flexible element in the transmission system and at one time used a spring coupling behind the gearset.

The top worm with worm wheel and differential is carried as a unit in the top cover of the cast axle casing; the latter has the sump integral, but has flanged and bolted-on extensions carrying the spring and brake brackets and the floating bushes of the wheel bearings. The wheel brakes are of the internal shoe type, with drums of 22 in. diameter and 3 in. wide.

This new Dennis chassis is unquestionably a sturdy job; it weighs slightly over 7000 lb. with solid tired, cast, hollow-spoked wheels, and is typical of the now medium but formerly heavy type of British truck. Its selling price is now £950, which represents a drop of £330 since its introduction.

One of the biggest of British truck makers and with a range of models already approaching a dozen—counting variations made available in five main types—Leyland has now put forward another model, a 3-tonner. This has a wheelbase of only 102 in. and an overall length of 192 in. It is of the full over-type, i.e., has the driver's seat and platform on top of the engine space, with a weather board in front. There has been a limited demand in England for a truck with a small turning circle and capable of being weighed both axles at once on any public weigh-bridge; and this new Leyland is put out to meet that demand. As with all over-type trucks, accessibility is sacrificed to a certain extent to obtain the advantages of the general arrangement.

The driver's platform is supported by an angle steel frame, forming the engine hood with detachable floorboards above and sheet steel sides, hinged as to approximately half their length. This frame carries the pedal shaft and, on the right, the gear shift and brake levers, but the steering column is continued through to the front right-hand corner of the main frame.

The four-cylinder  $4\frac{1}{2} \times 5$  in. engine is supported back and front by lateral tubes, passing through the upper half of the aluminum crankcase. The separate gearset is also supported by two tubular cross members at four points. Behind the gearset it is clear that this is not a model specially designed throughout, for one finds an open coupling shaft leading to a very short propeller shaft, the latter enclosed in a spherical headed torque tube supported by a bracket housing projecting rearwardly from a 3-in. diameter tubular cross-member of the frame. If the transmission had been specially designed, it is unlikely that a two-part propeller shaft would have been adopted, in view of the short wheelbase.

Final drive is by top worm, with a differential carrier forming the top section of the cast steel center of the axle casing. A departure from normal is seen in the semi-

elliptic rear spring mountings; each eye of the spring is secured to a slide block free to move fore and aft on frame brackets with horizontal surfaces which are shaped to a V at each side to dovetail into the slide blocks. The sliding surfaces are exposed, grease cup lubrication being provided. This chassis has different wheel tracks fore and aft; at the front the tire centers are 64 in. apart and at the back only 52 in. The chassis price is £1,000.

Commer has a new 6-ton model, but in the main it is merely an enlarged and strengthened edition of the 4-ton type, with a larger engine. The latter has a bore and stroke of 120 x 140 mm. ( $4\frac{3}{4} \times 5\frac{1}{2}$ ), pair cast L head cylinders, ball bearing crankshaft, thermo-syphon water circulation; all three items being standard Commer practice. The engine is three-point suspended on the main frame; there is a single longitudinal trunnion support in the cast front cross member, while the back end of the crankcase has a cast channel section two-armed bracket bolted to it and extending to the side frame members.

The induction tract is also unusual, for from the carburetor on the right to the valves on the left the mixture passes through a branched manifold to passages across the cylinder blocks below the water jackets and up to the valve ports.

Channel steel pressings form the frame side members, these being  $6\frac{1}{2}$  in. deep by  $2\frac{1}{4}$  in. wide between the spring hangers and tapering to  $4\frac{3}{8}$  in. deep at the ends; but a  $15/16$  in. adjustable truss rod is used under each side, anchored at the front to the rear spring bracket and at the rear to a special frame bracket some 12 in. behind the rear axle; there are two

struts, that at the rear being in line with the front hanger of the back spring. Transmission is by cone clutch, four-speed separately mounted gearset, and side chains. Commer's are made in six models, three having worm drive and three side chains.

An outstanding feature of Commer trucks has always been a type of gearset different from the normal sliding and selective system. Until lately the Lindley gearset has been used, in which the gears are constantly in mesh and brought into use by a rotating grooved cam which allowed spring-backed dog clutches to be engaged. But the Lindley set has been dropped and another special pattern is now standardized. This is of the selective type, giving four speeds. There are constant mesh wheels at each end of the box, and two sliding sleeves, each with two pinions and dog teeth at their ends; one sliding member is on the layshaft and is free to rotate thereon, the other moving endwise only on the splined main shaft. The various combinations are shown by the diagrammatic views herewith.

When the ratio is varied, the gear teeth are engaged when the gear on the layshaft is rotating idly and only its own inertia has to be overcome to vary its peripheral speed; not until its teeth had become two-thirds engaged are the dogs brought together. The dog teeth are stepped, beveled off and slightly undercut, and the arrangement is claimed to effect a great improvement in ease of gear shifting, both up and down; the gear teeth are not dam-

Circular racks operated by pinions on transverse shafts provide lateral movement for striking rod. 6—The tracket overhung from a tubular cross member to support the forward end of the Leyland torque tube. 7—Method of suspending rear end of engine and gearset unit on new 2,750 lb. Guy

aged if the driver is careless or incompetent and the dogs will stand up to rough treatment. To shorten the shafts, by having the gear wheels closer together, both sliding sleeves are moved when the third and top ratios are being engaged; this is simply arranged by having two striking arms on the lever shaft, one only engaging a selector rod for first and second speeds, but both being in use for either of the two higher ratios. This gearset is obviously somewhat more costly to make than the usual pattern, but for heavy trucks the slight extra cost may be justified.

Both the new 7-ton and the 4-ton Caledon models, the latter used mainly for bus work, are of the semi-over type, and are designed on the same general lines except that the lighter chassis has top worm drive as against the other's double chains. The engine on the big chassis is three-point suspended in the main frame by means of a trunnion bearing at the front and a cast steel cross member bolted to the crankcase at the rear.

As on the over-type Maudslay, the steering box is bolted to the front right-hand corner of the rolled steel

frame, the latter being 7 in. deep and 3 in. wide, straight from end to end. Engine accessibility is partially sacrificed to obtain the lengthy load space, the magneto, for example, being under the driver's footboard and needing a contortionist to inspect the contact breaker without removing the whole machine.

The four-speed gearset is amidships, three-point suspended from pressed steel cross members. The gear shift coupling between lever shaft and selector rods is novel; it should prevent jamming and binding, but is an expensive design, and hardly worth while when the same ends can be secured in a less costly manner. The lever shaft, which is 60 in. or so in front of the gearset, has a series of grooves or circular teeth near its inner end, which, when the lever is pushed across the "gate," rotate a pinion on a longitudinal jointed shaft having a similar pinion at its rear end, this second pinion serving to move another rack or grooved shaft which carries the selector finger or lever. Thus lateral movement of the gear shift lever is conveyed to the selector finger; the extreme inner end of

the shaft of the former carries a short drop lever, with a coupling rod to a corresponding lever on the selector shaft; this means enabling the gear sleeves to be moved as usual.

This chassis provides an 18 ft. (216 in.) loading platform with 6 ft. (72 in.) overhang at the rear.

The manufacturer of the Star has hitherto made three types of chassis all identical as to engine and gearset but varying in respect of weight and strength of frame, springs and axles. But the heaviest of these (3 ton) has been dropped and its place taken by a 4-tonner. The new type has a four-cylinder pair-cast detachable L head engine. Besides being peculiar in having detachable heads on pair-cast cylinders, it is notable in having the cylinder holding-down studs extended so that they serve also to secure the cylinder head along the right-hand side and center; on the left is the usual row of short studs and nuts. Threaded valve caps are provided in the head. With a bore and stroke of 127 x 140 mm. (5 x 5½ in.), this engine has a separate two-part aluminum crankcase with handholes on the right large enough to enable the piston and connecting rods to be withdrawn or fitted without displacing the sump. Helical gear distribution is

used with a transverse shaft driving magneto and water pump. Hollow shaft lubrication, cone clutch, four-speed gearset amidships (three-point suspended on a subframe), double reduction final drive, transmission brake on bevel pinion shaft, and internal brakes on rear wheels are other details of the design.

A two-part propeller shaft is used. Drive and torque are taken by triangulated pressed steel members leading from each side of the central casing of the axle to a spherical mounting below a pressed steel cross member of the frame. The price of this chassis is £960.

The name Sheffield Simplex has long been associated with private passenger cars, and at the October Show it was attached for the first time to a truck chassis. The latter is to be called the Shefflex and is intended for 1½-ton loads. It follows quite normal lines throughout, with pair-cast L head cylinders, 4 x 4¼ in. bore and stroke, thermo-syphon circulation, trough lubrication, magneto ignition, cone clutch, amidships three-speed gearset and Hotchkiss drive; but for the reputation of its makers for high-class work it would be hardly worthy of mention, so ordinary is it in general design and layout. The chassis is offered at £680.

## The Common Sense Cost Accounting System

**T**HE fact that many cost accounting systems have been worked out on a highly theoretical, but impractical basis was brought out in a paper read before the conference of the Industrial Cost Association, held in Pittsburgh recently, by J. M. Howell of the General Electric Company, Schenectady, N. Y. Many of these systems, Mr. Howell said, have broken down when confronted with the cold facts of business.

The paper went on to point out that industry has reached a point where it is no longer sufficient that a satisfactory cost system merely record expenditures already incurred, but it must also provide a medium for a positive control of these expenditures. Many cost investigations at present are but post-mortems over some important contract which, after completion, has shown an unexpected loss instead of the expected profit.

Cost reports, to be of real value to executives, must be rendered promptly. This is especially true at the present time with those which cover indirect or overhead charges. In general these reports in the past have gone into too much unnecessary detail and in most instances the essential facts could be shown in simpler and better form. In many cases the use of graphic charts would present the information in a more striking and convincing manner than the old methods.

The executive will find the report of little value, no matter how accurate and complete it may be, unless the records are maintained in such a way as to be readily available for compiling prompt estimates for quoting on new business. Nothing can more quickly demoralize a business organization than failure to accurately forecast the cost of production. Furthermore, the system cannot be considered as ideal unless provision is made for furnishing designers, superintendents or foremen with correct detailed information concerning relative costs of various materials, operations and processes.

The effective cost system will also provide for the immediate detection and segregation of any unusual expenditures, either in direct costs or overhead, in order that these may be considered separately in establishing selling prices. This is especially important in the manufacture of a standardized product. A ready-made cost system is seldom a good fit. The now somewhat obso-

lete method of applying a flat percentage rate to cover overhead, undoubtedly has its serious faults, but the other extreme of trying to determine the exact rate of overhead for each machine or tool in a factory also has its disadvantages and may be carried to a point where it is neither desirable nor practical. Most items of overhead cannot be definitely allocated, and must, therefore, be pro-rated on a common sense basis.

There are some cost systems, too, which require so much of the workman's time in keeping his accounts, that his productive capacity is decreased. No cost system should require much clerical work on the part of workmen, such as making out time cards, etc., but better results can usually be obtained by having regularly appointed clerks handle, as far as possible, all such work.

The properly balanced cost system must fit into other departments of the business organization. It must co-operate with the selling system in order to promptly and accurately forecast the cost of future production. The purchasing division must keep a steady stream of information flowing into the cost department concerning prices of commodities. The production, or shop routine, division, the designing engineers and the shop superintendents and foremen must all work with the cost accounting division. Failing in this functioning to the fullest extent in its relation to other departments the cost system is pretty apt to have a demoralizing effect.

In brief, the efficient cost system, to achieve the maximum of success, must be based on the fundamental principles of sound accounting procedure and good business practice. In respect to details it should be constructed along the lines of common sense and straight thinking as they apply to the particular business under consideration. This method will prove far more useful to the manufacturer than one in the use of which he allows himself to be guided by ready-made rules and forms.

**A** BOOK in which an effort has been made to list the number and size of piston rings used in every make and model of passenger car, truck, tractor, marine engine and stationary gas engine manufactured in this country has recently been published by the Gill Manufacturing Co.

# Automatic Brake Regulation to Prevent Wheel Locking

In one brake here described the braking action is dependent upon centrifugal force, which increases as the car speed increases and vice versa. French designers have recently been giving much attention to the servo brake which is applied by other than direct muscular pressure.

**I**N a previous issue of AUTOMOTIVE INDUSTRIES the statement was made that one of the features of this year's Paris show was the attention which had been paid by French and other Continental designers to the problem of effective braking. This was emphasized, for one thing, by the large number of firms which had adopted front wheel brakes or used four-wheel braking. There was, however, also another development in this line, namely, the adoption of brakes which automatically prevent the locking of the wheels, thus enabling the maximum retarding effect to be obtained and at the same time preventing injury to the tires.

A brake of this type, known as the Hallot brake, was exhibited on the Chenard-Walcker car at the Paris show, and has also been fitted to many other makes. They have been described by *La Vie Automobile*. The principle underlying the design of this brake is as follows: The brake consists of the usual drum and expanding or contracting member, but the drum, instead of being rigidly keyed to the wheel hub, is free to turn thereon. In addition to the above-mentioned parts the brake comprises a disk or spider which is fast upon the shaft to be retarded and takes the place of the web or spider of the ordinary brake drum. The rim of this disk is formed with recesses in which there are located centrifugal weights. These weights are lightly pressed against the inside of the brake drum by coiled springs

within them, and when the wheel is rotating they are pressed against the drum by the additional force of centrifugal action. The radial pressure due to the centrifugal force varies as the square of the speed of the car and is therefore very great at high speeds and very small at low speeds.

Now suppose that the car is proceeding at high speed and that the brake is applied. At first the brake band or sectors will slip on the drum, because the centrifugal weights now rotating at very high speed are applied with great force to the drum and hold it fast on the wheel hub. But as the speed of the vehicle decreases a point is reached where the friction between the brake band and the drum exceeds that between the centrifugal weights and the drum, and slippage will then occur between the latter parts.

## Wheel Locking Impossible

It will be readily seen that with this construction it is entirely impossible to lock the wheels, because as the wheels approach a standstill the centrifugal force on the weights becomes almost zero and the retarding effort practically vanishes. By properly proportioning the parts of the brake it is possible to limit the force of application to just a little less than required to cause locking and thus obtain the maximum retarding effect.

It is, of course, also necessary to be able to apply a

Fig. 1—Hallot automatic regulating servo brake as fitted to Bignan-Sport car. A, driving disk with recesses for the centrifugal weights; B, propeller shaft; C, centrifugal weights; D, spring applying centrifugal weight to floating drum with constant force; E, centering flange; F, floating drum; G, brake sectors; H, asbestos-fabric lining; K, disk supporting brake-operating mechanism; L, return spring; M, brake cam; N, brake arm; O, ball stud lever connected to brake pedal; P, hub of operating device for front wheel brakes; R, pull rod for front wheel brake; S, stop limiting motion of hub

Fig. 2—Diagram of servo-regulating operating mechanism for four-wheel brakes. A, pedal; B, pedal shaft; C, C', operating links of the servo brake band b; D, front wheel brakes; E, rear wheel brakes

retarding effect while the car is proceeding at low speed, as well as to be able to hold the car in position on a grade, and this is accomplished in the Hallot by providing a supplementary brake designed on the lines of the ordinary brake, but far from being sufficiently powerful to lock the wheels. At high speeds the braking power of the automatically regulated brake predominates, while at low speeds the auxiliary brake is the most powerful, and at all speeds the effects of the two brakes are cumulative.

### The Servo Brake

French designers during the past two years have also given some attention to what is known as the servo brake, by which is meant a brake which is applied by other than direct muscular power. Such a brake may be laid out in the following way: Consider a brake drum mounted on the propeller shaft; say, directly behind the transmission. A brake band may surround this drum, one end being connected to the operating member of the brake (lever or pedal), and the other to the rod which connects to the rear wheel brakes. If a pressure is exerted through the operating member of one end of the band, owing to the friction between the band and the drum, a much greater tension is exerted by the other end of the band on the brake rod, and this device therefore serves as a multiplying mechanism. The multiplying ratio can be made anything desired by varying the arc of contact between the band and drum. It is an easy matter to convert an ordinary servo brake into an automatically regulating servo brake. All that is necessary is to replace the keyed brake drum by a free-running pulley containing centrifugal weights on the inside, like the Hallot brake described above. In that case the multiplication of the force of brake application is automatically limited by the friction of the centrifugal weights against the drum and this friction automatically decreases with the speed of the vehicle.

Of course, the automatically regulated servo brake is supplemented by an ordinary brake. On the other hand, it may be so arranged as to act as a brake itself. That is, instead of serving merely as a multiplying agent for the force with which the brake is applied, it, in itself, may be used to exert a retarding action on the vehicle. This arrangement is made use of on the Bignan car, the brake lay-out of which is illustrated herewith.

One of the first manufacturers to use the Hallot brake in regular production was Chenard-Walcker, and the engineers of this firm are said to have achieved almost unbelievable results, stopping the car from a speed of 100 km. (62 m.p.h.) in a distance of 93.5 ft. without slipping of any of the wheels and without the least skid, the road conditions being specially favorable.

The advantages of the Hallot brake are illustrated by the curves shown herewith. At a speed of 50 m.p.h.

a vehicle fitted with ordinary brakes comes to a stop in 334 ft. Under the same conditions a car fitted with Hallot brakes stops in 195 ft. If the two full line curves are compared, it will be seen that the vehicle equipped with Hallot brakes lose speed much more rapidly. At the point where this vehicle comes to a stop, the other, with ordinary brakes, still has a speed of over 30 m.p.h.

All those familiar with the operation of high speed vehicles know that during the first few moments of brake application the reduction in

speed is hardly noticeable. Referring to the two curves (Fig. 3) of braking effort, for the ordinary brake it has a very low value to begin with, but increases little by little, becoming very large as the vehicle comes to a stop, when it is of no use. With the Hallot brake, on the other hand, there is a very considerable braking force right from the beginning, and it increases rapidly, tending to equal the adherence of the wheels to the ground. When this point is approached, and locking of the wheels

Fig. 3—Curves of braking effect with ordinary and Hallot servo brakes applied to the rear wheels only

is about to occur, the braking effort is automatically reduced. This strong initial braking effort obtained with the Hallot brake results in reducing the speed of the car from 50 to 22.5 m.p.h. in a distance of 131 ft., while the other car is still running at 37.5 m.p.h.

### Judges Appointed for Essay Contest

THE following men have been appointed judges to award the four-year university scholarship offered by Harvey Firestone for the best essay written on the subject "Good Roads and Highway Transport": Dean A. N. Johnson, Department of Engineering, University of Maryland; Harford Powel, Jr., editor of "Collier's Weekly," and C. H. Huston, Assistant Secretary of the Department of Commerce and president of the Lee Highway Association. The contest is open to all high school pupils in the country and is being conducted under the auspices of the Highway and Highway Transport Education Committee.

# Design Problems of the Isolated Electric Plant

Present difficulty is low efficiency energy transformations before usable power is obtained. Battery cost represents about 50 per cent of the initial output in 32 volt plant and also figures high in operating cost. Ultimate type of electric plant will be the full automatic, the author believes.

By Gustave Wiedeman

**T**HE difficulty which hinders the more extensive use of isolated electric plants, particularly for power purposes, is the larger number of low-efficiency energy transformations necessitated before usable power is obtained. For instance, the energy in gasoline or kerosene is transferred from a chemical to a mechanical form at approximately 15 per cent efficiency. This step is fundamentally necessary and cannot be practically eliminated or improved at present. Next, the mechanical energy of the engine shaft must be changed into electrical form by means of the generator, which is done at about 60 per cent efficiency. The transference of the electric current into storage battery energy requires a loss of 25 per cent. If now the current is used in an electric motor, 60 per cent to 70 per cent is the ordinary efficiency of the transformation. Thus it is evident that the over-all efficiency of the electric battery plant is very low and therefore extensive electric motor power use raises the cost of plant maintenance to a prohibitive figure. If power from a pulley of the electric plant can be utilized, the saving over the use of the same power from an individual electric motor drive amounts to approximately 73 per cent by reason of a 40 per cent generator loss, 25 per cent battery loss and further 40 per cent electric motor loss. In other words, it requires practically a 4 hp. plant engine to produce the power consumed by a 1 hp. electric motor, if run by the battery. Only 25 per cent of the plants made at present have engines as large as a 4 hp.

## Power Pulley for Power Purposes

The question naturally arises in this connection, "Why not use the power pulley exclusively for power purposes and dispense with all power-wasting individual electric motors?" In addition to the stock arguments advanced against it, such as immobility, belt troubles, etc., it is interesting to note that the actual power delivered at the pulley bears a widely varying ratio in the different models to the maximum power attainable through electric motor drives. The average excess engine power over generator output averages 60 per cent for plants designed for belt work and 35 per cent for plants not provided with power pulleys. In some cases the engine rated output exceeds the generator output by only 10 per cent, whereas the maximum excess is as high as 160 per cent, allowing in this estimate a 40 per cent generator loss. The engine output generally decreases materially as the engine becomes carbonized, the valves need adjustment, etc., and under such circumstances an engine will fail to rotate the generator under full load if the excess power ratio is as low as the figure stated above. We may be justified in concluding, therefore, that the power possibilities of a

plant can be most advantageously developed by using belt power in plants of high excess power ratio and confining light power work through electric motors to plants of low excess power ratio, where little is gained by having a power pulley. This latter condition holds particularly for full-automatic systems which are provided with an automatic generator cut-in, thus obtaining through electric motor drives for limited periods a discharge rate in excess of the normal generator output.

In designing an electric plant primarily for power use, it is evident that we face a problem essentially different from that met with in lighting plants. The power work with present plants is clearly limited by the great losses involved in the energy transformations necessary and very obviously the development of real power plants is interconnected with the evolution of some form of system which can eliminate the greater part of these losses.

## Battery Cost High

Finally, the power aspect of isolated electric plants presents a rather discouraging outlook from the battery standpoint. The battery cost of the average 32 volt plant now amounts to about 50 per cent of the total initial plant cost. Not only is the battery the element of the plant which requires the most frequent renewals but it also represents a large share of the plant cost. At present the average capacity of the battery at the generator rated capacity is about 5 hours, as stated above. If 5 hours of lighting and 5 hours of power work are averaged at normal generator capacity per week, it means 104 chargings per year, and, based on a battery life of 400 cycles, evidently such an installation would require a battery renewal in less than 4 years. At \$200 to \$300 per set of batteries, the cost per year for the battery alone aggregates \$50 to \$60, which just about equals the normal annual fuel costs. Thus it is evident that the power capacity of electric plants is limited by the capacity of its battery and since this is the big maintenance item, it is natural that electric plant engineers of the future should study this weakness of current design.

The electric plant industry is still in its infancy, a statement verified by the fact that about one-half of all plants produced have been made and sold within the last two years. This being the case, we cannot reasonably expect stability of plant design for some time to come. Even ten years of automobile development failed to settle such controversial questions as number of cylinders, two or four cycle, air or water cooled, chain or gear drive, etc. Similar issues are confronting the isolated electric plant industry, and a few of these are worthy of discussion from a commercially unprejudiced standpoint.

The most important of these is the matter of system voltage. On account of the ease and economy in securing lamps and other equipment, the 110 volt system would naturally be preferred for the ordinary installation. If the generating plant used is semi-automatic in operation, 56 cells are required for its battery complement and usually this item alone accounts for 50 per cent of the initial plant cost. Actually about 15 per cent of domestic plants are of this class. There are a few plants obtainable employing 60 volts, and the remainder of those using batteries, operate on 32 volts. The latter constitute the majority in current production which may be accounted for principally by the fact that such a system is the easiest to build and the cheapest to put on the market. Where a considerable area is to be covered with the lighting and power system, the cost of wire is an important item and for the same power varies inversely as the voltage. The copper cost of a 110 volt system is therefore only slightly more than one-quarter that for a 32 volt unit and the advantage in point of line loss is in the same ratio. Notwithstanding this fact about 80 per cent of present plants include 32 volt battery equipment.

### Choice of the System

Another of the important issues facing plant designers is the choice of system, whether manual, semi-automatic or full-automatic in character. Several full-automatic plant manufacturers have failed in the past, and their failure may have been influenced by imperfections in their automatic control mechanisms. At present there are four manufacturers producing full automatic plants, which employ only a low-voltage starting battery and deliver 110 volts D.C. to the circuit. About 10 per cent of all the units now on the market are full automatic but equipped with a 32, 60 or 110 volt battery. The remainder are about evenly divided between manual and semi-automatic control. The development of full-automatic systems have

made considerable headway in recent years and further exploitation in this field seems restricted only by the evolution of a simple, fool-proof full-automatic control, its desirability being self-evident.

Viewed from an impartial standpoint, it looks as though the full-automatic electric plant would be the ultimate type, irrespective of whether the voltage be 32, 60 or 110, and whether batteries are used or not.

### Increased Efficiency by Batteryless System

Judged apart from other considerations, the modern electric plant offers an inviting opportunity for improvement in the way of over-all efficiency. Consider the efficiency of the average 32 volt battery system from fuel tank to lamp socket. The best net over-all efficiency of the average four cycle low-compression kerosene engine is about 15 per cent; that of the generator 90 per cent; the battery, 75 per cent; and the line about 90 per cent. Multiplying these together we obtain approximately 9 per cent as the efficiency of the whole system. With the engine in the operating condition we ordinarily find it, as well as the battery and generator, 5 per cent would probably be nearer the true average plant operating efficiency. It is therefore rational that future design should develop the full-automatic batteryless plant which offers an immediate opportunity for improvement in at least two vital respects contributing to better plant efficiency, namely, (1) no battery loss and (2) less line loss due to the ability to use 110 volts (or 220 volts, for that matter). If in such a system we assume again an engine efficiency of 15 per cent, generator 90 per cent, and line 95 per cent, we obtain almost 13 per cent as the over-all efficiency or almost 50 per cent improvement over the low-voltage battery unit. It is encouraging to note that a few far-sighted manufacturers have already undertaken the perfection of the batteryless electric plant which carries with it the possibility of halving future operating costs.

## Tractor Used in Place of Locomotive

**A** LIGHT locomotive for use by lumber mills, coal and ore mines and other manufacturing plants is to be manufactured here by the E. T. Beatty Machine Co. The locomotive consists of a Ford tractor with special attachments. Three of the locomotives are now in use and are declared to be giving satisfaction, furnishing ample power and being very economical as compared with other types of locomotives.

The attachments consist principally of a steel frame and a set of four driving wheels. Power from the rear wheels is transmitted to those at the front by two connecting rods.

The frame of the locomotive is constructed of 1 x 6-in.

Fordson tractor converted for use as a locomotive

solid steel and will be standardized, while wheels will be available in a number of different sizes to suit the needs of the buyers. The locomotives can be reconverted into tractors at any time by removal of the attachment and replacing the tractor wheels.

**T**HE new German Patent Office law regulating fees, which has recently come into force, provides for considerable increases of fees, but consideration has been shown to poor inventors. The fee for the notice of a patent is now 100 marks, for the registration of a trade design 60 marks, as hitherto; for the extension of the validity of registered trade designs 300 marks and for registered trade marks 200 marks.

The annual fee for a patent for the first two years is 100 marks each, and increases by 50 marks per annum until the sixth year; by 100 marks per annum from the seventh year to the eleventh year, and by 150 marks per annum from the twelfth to the fifteenth year, so that in the last year of a patent the charges will be 1,400 marks. The fee for lodging a complaint will henceforth be 100 marks and for the renewal of a trade mark 50 marks.

It is hinted that a revision one way or the other may be called for when the financial results of the new rates have had time to show the effect.

# An Analysis of Air Bleed in Carbureter Compensation

The bow-shaped economy curve which usually results from the conventional dynamometer test is believed to be ideal. A flatter curve may indicate loss of power resulting from too lean a mixture. Various arrangements of the air-bleeding orifice are discussed and their effect is noted.

By W. H. Weber\*

**I**N carbureter literature a good deal may be read about "compensation," and the question naturally arises, "What is compensation and why do we need it?" The latter part of the question is very easily explained. It is only necessary to drive a car equipped with a simple suction-controlled, single jet carbureter to find that the mixture becomes richer as the engine speed increases. We may adjust the mixture in any way we like, but we cannot overcome this tendency for the fuel to flow faster in proportion to the air as the suction increases. The former question is not so easily explained.

Fig. 1 illustrates the first question, the horsepower and economy curves being records of dynamometer tests under wide open throttle made with a simple suction-controlled fuel jet and fixed air carbureter. If we bleed air into the fuel nozzle above the normal level of the fuel and duplicate the test in Fig. 1 we will get an exactly similar economy curve, showing that we have in no way altered the characteristic flow of the simple suction-controlled jet. It is a fact that such an air bled jet can never be compensating. The effect is merely that of an air spray over the fuel helping atomization as the fuel is lifted out of the nozzle.

The dictionary tells us compensation is reparation, intimating that there is a condition requiring correction

\*Engineer, Claudel Carburetor Company.

Fig. 1

which is the case in the plain tube carbureter. The distinction between air bleed and compensation is not generally understood, nor is the allowable percentage of air bleed generally known. The terms "air bleed" and

Fig. 2

compensation are synonymous only when the effect of air bleed is to alter the characteristics of the simple suction-controlled fuel jet.

It will be noted that the economy curves obtained with the simple suction-controlled fuel jet and air bled jet are of the straight line ascending type, but that the ideal economy curve is bow shaped, a little richer on both ends than in the middle. Only wide open throttle conditions are considered, because, as I indicated in my article, "Some Factors Entering Into Carburetor Construction," it is a simple matter to combine two suction controlled jets such that the suction increases on the one as it decreases on the other as the throttle is opened. This carburetor will satisfy level road, variable throttle driving, but it will fall down on hill climbing or where maximum power is desired at low engine speeds. We must accept the bow-shaped curve as ideal, for the simple reason that practical dynamometer experiments always establish such a curve. When we try to make the curve more nearly horizontal we lose power and the mixture becomes too lean to run.

This bow-shaped economy curve is obtained in plain tube carburetors by means of a compensating air bleed. To illustrate, Fig. 2 may roughly represent a discharge nozzle. The nozzle outlet B terminates at the throat of the venturi X. The calibrated fuel orifice C is submerged and the air bleed hole A above the level communicates

directly with the atmosphere. When A is closed we get the economy curve illustrated in Fig. 1 and when it is opened we get economy curves similar in shape (ascending) regardless of the size of opening A. This is a case of pure air bleed, no compensation. Now if we move A so that the orifice pierces the nozzle below the normal fuel level we get immediately a bow-shaped economy curve, the inclination of the bow depending directly upon the distance between the fuel level and A' and the size of calibration C. We have an air bleed just as before, but we have changed the characteristic simple suction-controlled fuel jet curve. The reason is that we have introduced a second flow not dependent upon suction but constant per unit of time. This flow is due to head, since the fuel level drops in the nozzle to the position of A', and where before we had only the effect of an air bleed causing partial suction destruction, we have now the same suction on the fuel plus an additional flow by virtue of the fact that a difference in head exists between the fuel supply or float chamber and the fuel discharge or nozzle.

Fig. 3 illustrates the effect of lowering the position of A without changing its size. It will be noted that the resultant mixture is richer the lower we place A. It might be added that a much more effective method of increasing flow due to head is to increase the size of the fuel calibration C, since flow due to head varies directly only as the square root of the head, but as the square of the diameter of the orifice. It might be argued that such a change would affect the mixture throughout the range, and more especially at high speeds, when the amount of flow due to suction is so much greater than that due to head, but we have a very good method of

Fig. 3

offsetting the former flow by simply reducing the size of nozzle outlet B.

The plain tube carbureter is a very flexible instrument in that we may get any number of different results by juggling openings A, B and C.

A very definite and important ratio exists between outlet B and air bleed or compensating air area A, which is not generally known. In a large number of tests I varied the ratio of B/A from 0 to 1, or made the change from simple suction-controlled jet to 100 per cent air bleed, and discovered the surprising fact that when B/A is 20 per cent or less we may expect maximum power, but when we go beyond 20 per cent—that is, when the air bleed area is greater than 1/5 the nozzle outlet area—the power falls off and it is not possible to regain the power lost by increasing the size of fuel jet C. This is equally true of air bleed or compensation. In road work we may go as high as 50 per cent when extreme economy is desired, but only at a sacrifice in power.

## Municipal Transportation Improvements

THREE recommendations of importance were submitted to the American Society for Municipal Improvements by the Committee on Traffic and Transportation. The first called for the installation of motor bus routes in municipalities when an extension of the public passenger transportation system is required, the second condemned the so-called "jitney service," and the third recommended the formation of a Highway Transport Division in municipalities with a population of 100,000 or more.

Installation of motor bus routes has resulted in advantage to many cities. Such a service not only maintains the maximum practicable traffic capacity of streets, but it also avoids the use of car tracks in the highways.

From the standpoint of economic public service transportation, the installation of "jitney" service is undesirable. The systems not only overcrowd the streets, the report said, with five-passenger public transportation vehicles, but "it is obviously unfair to public service corporations, operating under franchises, to be forced to compete with a 'jitney' service which almost universally is operating on an uneconomic basis." Detroit was cited as an example of crowded streets as a result of this service.

The duties of the Highway Transport Division, as recommended by the committee, would be to deal with all matters pertaining to traffic and transportation which affect the economic design and maintenance of streets and their efficient use by pedestrians and all classes of vehicles. An important function would also be to make highway transport surveys preliminary to the design or

redesign of streets. This survey would also determine efficient methods of maintenance and the formulation of recommendations pertaining to efficient traffic regulations. Many things would have to be taken into consideration in such a survey, such as possible future developments of the community with a view to determining the sort of traffic the road would be called upon to bear. Men assigned to this work should be experienced highway engineers who have a knowledge of practically all subjects related to highway work.

## Sulphide Liquor as Dust Preventive

IN Switzerland very good results are claimed to have been obtained from the use of sulphide liquor as a dust preventive on roads. The liquor is usually distributed by means of motor-propelled sprinkling carts. After the water of the solution has evaporated there remains a brown, shiny, asphalt-like residue, consisting mainly of lignin or ligno-sulphite, which covers the road material with a hard, adhesive liquor, and in case of sufficient thickness prevents the formation of dust for weeks. The effect is the more lasting the heavier the application, and the application is the surest of results if made before any dust has formed. About 400 cu. ft. of the liquor are required per mile of road 14 ft. wide. In order to reduce the freight charges the sulphite liquor is sometimes obtained in a concentrated form and diluted at the point of use. In contrast to tar, the lignin mass is soluble in water, so that continued heavy rains may wash the coating off.

# Some Road Tests with a New Type of Accelerometer

Measurements of tractive effort, tractive resistance, braking effort and brake hp. of two trucks and two passenger cars indicate some reasons why there is a marked difference in performance of various vehicles.

By Samuel H. Woods\*

IT is generally agreed that experimental data relative to automotive equipment should be taken under conditions of road operation, so far as possible. In laboratory work so many of these conditions can be only approximated or not realized at all, that results so obtained are frequently subject to criticism on this account. Any means, therefore, of obtaining reliable data while actually operating on the road is to be welcomed as a valuable contribution to the art of automotive engineering.

An instrument by the use of which it is possible to obtain not only data on engine performance in actual road operation, but also data on tractive resistance, has been tried out by the International Motor Co. in a preliminary way and so far appears to function well. It is known as the Drewry Testometer and consists of a U-tube of uniform bore, set with its plane level when the vehicle on which it is mounted is on a level surface. One branch of the tube connects with top and one with the bottom of a closed reservoir containing a colored liquid. In manufacture, the tube is carefully set level and the reservoir filled until the liquid just reaches the center of the bend in the tube, after which the top of the reservoir is sealed, forming a closed system.

It is obvious that if the tube is now inclined endwise, the liquid will come to rest in one branch or the other of the U-tube at a distance from the end depending upon the angle of inclination. If the tube and reservoir complete, mounted in its case, be set successively at different angles, and the positions of the end of the liquid column be marked, a scale will be obtained, enabling the device to be used as an inclinometer. This, however, is distinctly a secondary use.

If we consider the instrument mounted on a vehicle weighing 10,000 lb. standing on a grade of 1 in 10 (British nomenclature), neglecting friction, the brakes hold with a retarding force of  $\frac{1}{10} \times 10,000 \text{ lb.} = 1000 \text{ lb.}$ , or 224 lb. per ton (2240 lb.). It is on this basis that the instrument is calibrated, and if one analyzes the forces acting, it is not difficult to understand that this instrument will indicate at any instant the resultant accelerating or decelerating force acting on the vehicle in the direction of motion in terms of pounds per ton of its weight.

In order to understand that the instrument indicates true value of tractive resistance and tractive effort, regardless of the gradient, it is necessary only to conceive of the vehicle mentioned moving at uniform speed on the level and also on a grade. On the level the instrument will indicate zero because the engine is just overcoming tractive resistance. On the grade the indication will be the same as if standing at rest on the grade, and the engine will be overcoming tractive resistance and also raising the vehicle up the grade. When coasting down a grade the vehicle may accelerate, but we still get a true indication of tractive resistance, for the vehicle is free to move except for the retarding effect of this resistance.

The experiments were made with vehicles of widely varying weights and characteristics as shown on the charts. They consisted of—

1. Observation of tractive resistance on
  - (a) Fair granite block pavement,
  - (b) Smooth asphalt, at various speeds;
2. Observation of
  - (a) Tractive effort with full throttle opening,
  - (b) Tractive resistance,
  - (c) Tractive resistance plus engine friction, at various speeds;
3. Observation of maximum tractive effort in first, second and third speed.
4. Observation of maximum braking effort with each set of brakes.

In making these observations, the procedure was, first, to level the instrument relative to the surface on which the vehicle stands. To observe tractive resistance it is necessary to select a stretch of level road of uniform character as free as possible from undulations. The vehicle is brought up to a speed 3 to 4 miles per hr. in excess of the highest speed at which it is desired to take observations. The transmission gears are then placed in neutral position and the vehicle allowed to coast. As the vehicle slows down, the testometer reading at any speed is the value of tractive resistance in pounds per ton of vehicle weight. This, of course, includes rolling friction of the tires on the road and chassis friction.

The best method of observing brake horse-power is to select an up-grade which the vehicle will not quite climb in high gear. Starting at the bottom at the maximum speed desired, observations of tractive effort which is now indicated on the instrument are taken at various speeds as the vehicle slows down. To these must be added tractive

Diagrammatic view of the Drewry "Testometer," the form of accelerometer with which the tests here reported were made

\*The author is connected with the Engineering Department of the International Motor Co., on whose behalf the tests here described were made.

Horsepower, torque and tractive resistance curves plotted from results of tests made with the Drewry "Testometer" on four different vehicles

Franklin passenger car..	3,440	3.69	R-Howe cord, L.-Goodrich Silvertown cord, 34 x 4 1/2	40	Kelly-Springfield cord, 34 x 4 1/2	50
Ford sedan .....	2,770	3.67	Goodyear All Weather, (fabric), 30 x 3 1/2	60	Goodyear All Weather (fabric), 30 x 3 1/2	60

resistance values obtained by allowing the car to coast down the hill and observing instrument readings at various speeds as the car accelerates. If instead of coasting with transmission in neutral, the ignition is cut off and transmission left in high gear, we obtain values which include friction, and by adding these to those of tractive effort, we obtain approximate indicated horse-power.

The values of horse-power may be obtained as follows: Let  $P_t$  = maximum tractive effort plus tractive resistance in pounds per ton at a speed in miles per hour =  $V$ , while  $W$  = vehicle weight in tons of 2240 lb. Then,

$$\text{B.hp.} = P_t WV \times \frac{5280}{60 \times 33,000} = \frac{P_t WV}{375}$$

and, if  $P_i$  = maximum tractive effort plus tractive resistance plus engine friction, I.hp. =  $\frac{P_i WV}{375}$

Engine torque is obviously total engine effort =  $(P_i WR) \div K$ , where driving wheel radius =  $R$ , and the gear ratio =  $K$ .

In all cases in which this instrument is applicable, care must be taken to use it in such a way that its indications do not change rapidly. This means that in observing values of tractive effort, the grade should be such as to permit the car to accelerate or decelerate slowly with wide open throttle. When tractive resistance is being observed, variable winds seriously affect readings on light vehicles. Unevenness in the road surface causes rapid fluctuations in the indication. If the air is still, a slight down-gradient is an advantage, but if windy so that runs must be made in both directions, a level road is preferable.

The curves attached show results obtained in the first experiments made with this instrument by the International Motor Co. To a great extent these are self-explanatory, but a few comments will aid in their interpretation. Tractive resistance will be seen to include chassis friction and rolling friction. In routine factory testing, therefore, the instrument should be of great service in

keeping the former within limits which can be established after sets of readings have been taken on a number of chassis over the same road surface. Various types of road surfaces, again, can be compared from tractive resistance indications taken upon them, using the same vehicle in each case.

It is to be noted that only one set of observations was made in obtaining the horse-power curves. By taking several sets of readings and averaging, a smoother result would be obtained and the effects of road irregularities minimized. This principle applies to all readings taken with the instrument; in order to obtain satisfactory results the average of several runs must be obtained. Great accuracy of speedometer readings is also essential.

Measurement of braking effort is a very useful function of the instrument. Taken in conjunction with tractive resistance, readings on braking effort indicate whether or not brakes drag when released, and their effectiveness when applied. Net braking effort is, of course, that indicated less the tractive resistance value at the speed at which the car is traveling. In order to be fully comprehensive, a fairly steep grade should be selected for the observation of braking effort. This in order to arrive at the values at different speeds as the car slows down, more gradually than it would on the level.

Values of maximum tractive effort, also, in order to be of greatest usefulness, must be observed under conditions which reduce the acceleration so that simultaneous readings of speed and tractive effort can be made with reasonable accuracy.

Braking effort and maximum tractive effort were observed so far as possible without undue expenditure of time, on the 7 1/2-ton truck and the Franklin touring car, with the results given below:

	Maximum Tractive Effort Lbs.-Ton			Maximum Braking Lbs.-Ton	
	1	2	3	Foot	Hand
7 1/2-ton Mack .....	380	200	140	340	215
Franklin .....	312	260	140	260	260

These values are undoubtedly low, since all except those of tractive effort with the truck were taken on a level road and the changes of indication in the instrument were too rapid to permit of great accuracy. Where an engine is governed as in the truck, the observation of low gear performance is almost impossible except on a very steep grade because of governor action.

The values of tractive resistance as shown in the curves indicate a wide difference for the various vehicles experimented with. This difference is obviously due to a com-

bination of chassis and tire friction. The exact relation of these does not yet appear. It is obvious, however, that the difference between pavements 1 and 2 is due to a difference in tire friction. It will be noted also that in the cases of the lighter vehicles a slightly more rapid rise of the curves above 15 m.p.h. is shown, indicating the effect of wind resistance. Such curves will undoubtedly be of great service in studying the effects of different types of tires and varying the elements of chassis friction through gear and bearing adjustments and lubrication.

## This Year Progressive in Federal Aid Highway Work

THE amount of money expended by the various states for highway improvement during the fiscal year ending last May 30 was nearly double the amount spent in the four previous years.

This fact is shown in figures giving the amount of the \$226,000,000 appropriated by the Federal Government for road work the states have used since the money was made available. During the four years previous to May 30, 1920, but \$40,097,881 had been taken over by the states and between that date and May 30, 1921, a total of \$38,719,134 was dealt out to the various state governments, making a total of \$78,817,015. By last midsummer the Bureau of Roads estimated that there was but about \$18,000,000 left of the original appropriation, for a vast number of projects were taken over during the summer months. Work on many hundreds of these new highways has already begun and is now being rushed. It was shown that by June 30 twelve states had completely exhausted their quotas of the money and many others had but enough remaining to permit building but a mile or two of road. Here and there were delinquents, but as a whole the states surmounted the tremendous obstacles they found in road building and co-operated with the Government in its endeavor to get improved roads built by sharing half the expense.

June of 1921 saw 1200 miles of highways (Federal aid system) completed—about twice as much as the record for May showed. The accomplishments for these two

months together nearly equaled the total completed mileage for the previous four years. The old record of 1677 miles of the 1920 May Bureau of Roads reports for finished miles had grown to 7469.

Especially rapid progress has been made in some of the Middle Western States, Indiana being an exception. By midsummer Illinois had completed 411 miles of its Federal aid roads and was spending \$12,265,218 (estimated) on 334 miles of additional roads—hard surface ones largely. Ohio, with 182 miles finished, was spending \$15,319,521 to complete 404 miles; Wisconsin had 255 miles done and had \$9,844,248 of contracts calling for 644 additional miles—a considerable quantity of this mileage of gravel, and other types. Michigan, with 105 miles of completed work, had 280 miles under construction at an estimated cost of \$8,319,920. On the same date these records of June 30, 1921, show that Indiana had finished 21 miles, and had 137 miles under way at an estimated cost of \$4,959,948. Her original apportionment was \$7,415,298, and the May 31 records show that at that time she had left to her credit, and unobligated by approved projects, \$4,545,499. She has since filed a number of projects, but not nearly enough to come within millions of her share. She may yet have a chance to obtain the money the Government set aside for her several years ago. At any rate, she has the greatest opportunity of all these of doing much work at Federal expense right now and thus relieve to some extent the unemployment situation there.

## Motor Taxation in England

A PLEA for heavier taxation of motor trucks in England was uttered recently before the Institute of Transport by E. A. Brookes, surveyor of the Durham County Council. Mr. Brookes declared the present funds available for highway maintenance were insufficient and additional revenue would have to be provided. It was pointed out that it was to the interest of the owners of these heavy vehicles that additional funds be obtained, as improved highways would result in less wear and tear upon their trucks.

Some interesting figures were brought out in the discussion, among them being statements showing that self-propelled traffic on some English roads has increased from 45.1 per cent of the whole in 1912 to 92.3 per cent in 1920, and that the traffic of heavy motors has increased from 21.6 per cent in 1912 to 51.5 per cent in 1920. It was also declared that since 1912 the total traffic in weight has increased by about 290 per cent.

Mr. Brookes, in his argument, said the present fee of 39 pounds per year was inadequate and said vehicles should be taxed one penny per ton mile.

An interesting point was brought into the discussion, however, when it was declared that the term "road user"

was given too narrow a meaning, being applied only to the owner of the vehicles using the roads. The persons to whom, or from whom the goods were being delivered, it was pointed out, also fall in the category of road users, for they benefit by the motor truck delivery. Roads also increase the value of land facing the highways and the general taxpayers should be made to bear a part of the burden for their upkeep.

Apparently the situation in England somewhat reflects the situation in this country. If registration fees are increased it can but mean that the consumer must ultimately pay the difference. These fees, in many states, are the sole funds available, other than the federal appropriations, for road improvement, whereas as a matter of fact the farmer whose land faces the improved highway is greatly benefited in that the value of his land is increased, the merchant is benefited in that more goods can be delivered over the roads and more people from a distance are able to come into his stores and in fact all branches of industry are benefited by better roads.

Yet the burden of maintaining these roads bids fair to fall, to a large extent, upon the shoulders of the owners of heavy trucks.

# Transmission Standardization

Establishment of reasonable limits of parallelism and concentricity between flywheel, motor housing and transmission case is important. Manufacturers stand in their own light by refusing to adopt S. A. E. standards.

**S**OME of the most important parts of transmission gearsets have been standardized by the S. A. E., including the splined shafts on which the gears slide and the corresponding broached holes in the gears, the bell housings, the shaft ends and the tire pump mounting. There remain, however, a number of other features on which—manufacturers feel—standardization work could be done to advantage. What the problems are that confront the manufacturers of transmissions was well brought out in the report of the Transmission Subcommittee of the A. G. M. A. Standards Committee submitted at the recent Rochester meeting by W. H. Lyman of the Warner Gear Co.

Mr. Lyman considers that there are still too many types and sizes of bell housings for unit power plants. He admits that much creditable work has been done along the line of standardizing bell housings by the S. A. E., but unfortunately many car builders do not make use of the standards already adopted and stand in their own light in an effort to reduce cost of production and to meet competition.

The matter of establishing reasonable manufacturing limits of parallelism and concentricity between flywheel, motor housing and transmission case deserves serious consideration. The transmission manufacturer may hold his own work within reasonable limits, but the transmission may be secured to an engine in which the bored hole for the pilot bearing in the flywheel is oversize and not concentric with the snap fit in the crankcase; or, on the other hand, the bore of the crankcase for the transmission flange may be oversize, eccentric and out of parallel with the flywheel. Such misalignment of motor and transmission causes undue bearing wear, transmission strains and gear noise.

Misalignment will also produce a hard-working, grabby clutch action. This is particularly true of the gear-tooth, multiple-disc type of clutch, where there are so many points of contact and where it is necessary to hold the back lash reasonably close to prevent clicking of the teeth on the discs against the teeth cut in the flywheel or in a driving drum fastened to the flywheel. Mr. Lyman said that he had seen many flagrant cases of misalignment of transmissions and engines. For instance, engines where the face of the flywheel to which the clutch driving drum is attached and the face of the crankcase to which the transmission case is attached out of parallel as much as 0.070 in., and the bore in the crankcase to receive the snap fit of the transmission oversize and out of round as much as 0.045 in. Under such conditions it is no wonder that we have clutch trouble and noisy transmission gears.

It is admittedly somewhat easier to hold to close limits on the flange of a transmission case than it is on an engine crankcase, but reasonably close limits may be expected on the part of engine manufacturers. It is proposed that the A. G. M. A. Standards Subcommittee on Transmissions, the Engine Manufacturers' Association and the S. A. E. get together and work out a set

of reasonable tolerances that will insure good working conditions in the clutch, engine and transmission.

One of the problems which the new committee has set itself is to formulate recommended practice regarding center distance, width of face, pitch and pressure angle of gear teeth for given ranges of engine torque. In Mr. Lyman's opinion this problem should be approached carefully. For instance, his company has found it easier to produce quiet gears from oil-hardening than from case-hardening steel, owing to the lesser distortion during heat treatment of the former, and as quiet operation is such an important factor in gear work, the kind of steel to be used should be settled first.

The maker of transmission lubricants and the makers of transmissions have not worked together very closely. The automobile builder discovers that the lubricant he has been using during the hot and mild weather will not answer his purpose during the cold weather, because his customers complain of the hard shifting of gears, so he calls for help from some oil man and, sure enough, the oil man can help him out and furnishes a grade of lubricant that makes the gear shifting somewhat easier but in doing so the change of lubricant produces a howl in the transmission that was formerly quiet with the old grade of oil used. Now, instead of the car builder going after the oil man to meet a gear condition, he goes after the transmission builder to meet an oil condition. Some of the lubricant is so thick that it will not run out of a bucket turned upside down and surely lubricant of this consistency will not penetrate the small hole made in the stems of some designs of drive gears for the purpose of lubricating clutch bearings or other parts. Some improvement in this situation can undoubtedly be made by co-operation between the transmission interests and the oil people.

Another subject that deserves study is the best form of gear blanks. These blanks should be of such form that they can be easily manufactured and there should be no extreme heavy and light sections, as gears of that type usually distort heavily under heat treatment. In the case of small diameter gears with keyways in them, attention should be given to the amount of stock left over the keyway, to see that there is sufficient to prevent cracking.

The subject of wall thickness for transmission cases appears to be in a very chaotic condition at the present time, as wall thicknesses of 3/16 in. to 9/16 in. may be found. With a transmission of given capacity and number of speeds the cases of transmissions are very nearly alike in form and size, and there cannot possibly be such a range in the requirements of wall thickness as indicated by the above figures. The limits on the light side depend somewhat on the ability of foundries to produce sound castings and partly on the requirement of noiseless and vibrationless running, which characteristics are favorably affected by heavy walls. If any standardization of wall thicknesses is attempted it will be done in consultation with good reputable foundries.

# Germany's New Standardized Motor Fuel

Mixture of benzol and alcohol with tetralene has produced excellent results in road tests and races. Can be used with ordinary type of carbureter with no change in the fuel nozzle. Attempts to use tetralene alone proved unsuccessful, which led to government's adoption of the present standard.

By Benno R. Dierfeld

WITH the precipitous decline in the exchange value of the mark, Germany before long will be unable to buy any foreign motor fuel and will be compelled to use fuel of native production. A suitable home fuel for all kinds of motor vehicles is benzol, but, unfortunately, the quantity available for home consumption is inadequate. Another by-product of the German coke industry is naphthalene, which can also be used as fuel in internal combustion engines, but the fact that it is a solid at ordinary temperatures makes it necessary to use complicated devices for preheating, which makes it inconvenient for motor vehicle use.

During the war German chemists succeeded in converting solid naphthalene by catalytic hydrogenation into tetrahydronaphthalene, called tetralene for short. It is a liquid at ordinary temperatures and is produced at the rate of 100 tons and more per day by the Tetralin Co., Berlin W-8. This tetralene, with its high boiling point,

Fig. 1—Diagrams of Molecular Structure

is especially adapted for vehicle engines using a high compression ratio, because it is free from knocking tendencies. Tetralene ( $C_{10}H_{12}$ ) is a uniform chemical compound, and its molecular structure may be represented by the diagram shown at the right in Fig. 1. This structure may be compared with that of the naphthalene ( $C_{10}H_8$ ) from which it is made, as shown at the left in the figure, the transformation consisting in the addition of four hydrogen atoms to each naphthalene molecule.

As stated, tetralene is a liquid at ordinary temperature, water-white in appearance, of a specific gravity of 0.975. Its boiling point is 205 deg. Cent. (452 deg. Fahr.) and its point of solidification or freezing point is very low, minus 30 deg. Cent. (minus 22 deg. Fahr.). The calorific power of 11,600 kilogram-calories (20,900 B.t.u. per lb.) is very high, and the high flash point of 79 deg. Cent. (174 deg. Fahr.) insures safety in operation. Tetralene is not suited for use by itself in present types of aircraft and automobile engines, but by mixing it with fuels of a lower boiling point it can be used with-

out difficulty in the average vehicle engine. The admixture of these fuels with tetralene also lowers the specific gravity, whereby the necessity for changes in carbureter adjustment is obviated. Exhaustive tests in the Motor Laboratory of the Berlin Technical University by Dr. Schrauth and Diplom-Engineer von Keussler conclusively proved that very good results may be obtained with a mixture consisting of equal parts (by weight) of tetralene and gasoline, having a specific gravity of 0.720 to 0.735. According to Wa. Ostwald, a well-known chemist, a mixture consisting of equal weight parts of tetralene and benzol is an excellent fuel for motor cars and can be used without change in the fuel nozzle.

An important fact in this connection is that alcohol may be added to such tetralene-benzol mixtures in almost any desired proportion, as the addition of alcohol, on account of its water content, influences the combustion of the tetralene in a favorable manner. For this reason a tetralene-benzol-alcohol mixture seemed to be the most suitable fuel of home production for use in Germany. There is at the disposal of the German Government about 60,000 tons of benzol annually (provided only the standard benzol is used in the future); the tetralene works can produce 30,000 tons of tetralene annually and the Government might release 30,000 tons of alcohol for motor fuel purposes. This would yield a total of 120,000 tons of home motor fuel per year, or more than required by German motorists.

The new German standard fuel, called *Reichskraftstoff*, has the following composition (by weight):

50 parts benzol—25 parts tetralene—25 parts alcohol.

The name and composition are due to the noted chemist, Walter Ostwald. The specific gravity of the standard fuel, 0.865, is about the same as that of benzol, and its heat value of 9000 calories per kilogram (17,200 B.t.u. per lb.) or 8000 calories per liter (54,400 B.t.u. per gal.) is quite satisfactory. A new method of preparation has been developed which overcomes the tendency of the components to separate out when the mixture is cooled off or when benzol or water is added.

The distillation curve of the new standard fuel is most favorable and is shown herewith (in comparison with a distillation curve of gasoline as now sold in the United States.—Editor). The following table gives the proportions that pass over at different temperatures:

Per Cent (Volume)	Deg. (Fahr.)	Per Cent (Volume)	Deg. (Fahr.)
0—10	149—156	60	248
20	162	70	285
30	162	80	379
40	167	90	392
50	189	95	400

Up to 212 deg. Fahr. 54 per cent of the mixture passes over, and boiling begins at 147 deg. Fahr. Not less than 45 per cent of the mixture passes over at temperatures less than the boiling point of the most volatile constituent. It will thus be seen that in this case a mixture of very good vaporization qualities is obtained from components of comparatively high boiling point.

This standard fuel can be used in all ordinary carbureters without change in the fuel nozzle, but the air should be pre-heated to a somewhat higher temperature than with gasoline. Draining of water from the fuel strainer, as customary with gasoline, is not necessary, as the standard fuel dissolves water, and no trouble is experienced from water in the fuel. As the standard fuel is heavier than gasoline, with the same fuel nozzle the consumption will be less. Starting of the engine involves hardly any more difficulty than starting on gasoline. It should be specially emphasized that this new fuel is no emergency fuel, like the numerous fuel mixtures mentioned by the writer in a previous article in AUTOMOTIVE INDUSTRIES of Sept. 9, 1920, but is a convenient and all around satisfactory fuel that will be able to hold its own in competition with gasoline and benzol when the latter are again available in sufficient quantity.

An important factor in connection with any new fuel is the cost. In making a comparison with other fuels it is not proper to do so on the basis of the cost per unit weight or volume; what should be compared is the cost of a certain number of heat units obtained from the different fuels compared. The following table gives the data necessary for such a comparison (all figures relating to costs in Germany only, it has not been deemed necessary to convert them.—Editor.)

	Gasoline	Benzol	Tetra- lene	Alcohol	Stand- ard fuel (50-25-25 mixture)
Spec. gravity....	0.725	0.860	0.975	0.810	0.865
Heat value in calo- ries/kilogram ..	11,000	9,700	11,600	7,200	9,000
Heat value in calo- ries/liter .....	7,980	8,440	11,300	5,830	8,000
Retail price in marks per kilogram (August, 1921).	8.50	5.60	7.40	6.50	6.25
Price of 1000 calo- ries in marks...	0.77	0.58	0.64	0.90	0.69

As to the consumption with the new standard fuel, the tests of Professor Dr. Schrauth are interesting. For instance, a 35 hp. car, the Zenith carburetor of which was adjusted for gasoline, consumed on a run of over 1100 kilometers (685 miles), at an average speed of 40 to 45 km. p. h. (25-28 m.p.h.), only 12 liters or 10.6 kilograms per 100 kilometers (19.6 miles per gal.) with the standard fuel, while the consumption of gasoline of 0.730 specific gravity was 19.8 liters or 14.5 kilograms per 100 kilometers (11.9 miles per gal.). Other cars had similar consumption. With the standard fuel all cars

Distillation curves

showed very good performance, good starting and acceleration, and no popping in the carburetor in cold, moist weather. The highest car speed, which was 90 kilometers per hour (56 m.p.h.) with gasoline, could be increased up to 100 kilometers (62.2 miles) per hour with standard fuel. During the period, Oct. 4 to Oct. 7, the Allgemeine Deutsche Automobil Club, the largest German club, with 25,000 members, arranged a long road race for motorcycles and light passenger cars up to 24 hp.; for all vehicles the standard fuel was prescribed, and good results were obtained. Now the German government has adopted the new standard fuel and ordered its sale instead of that of pure benzol at the government fuel stations.

## Gasoline from Vegetable Oils

IN a recent issue reference was made to experiments by M. Mailhe in France with a view to making gasoline from vegetable oils. The item was not as clear as it might have been. A note presented by M. Mailhe to the French Academy of Sciences fully describes the process employed.

It is well known that the fatty oils cannot be distilled at ordinary pressures without partly decomposing. It occurred to the author that it might be possible to break them up more completely in contact with catalyzers mixed with both hydrators and hydrogenizers, at a temperature of 1000 to 1200 deg. F. To this end one can use to advantage electrolytic copper combined with magnesia, alumina or caolin. The mass is formed into balls with the aid of a binder. These balls are heated in a copper tube. At one end of this tube the linseed oil enters through a capillary tube. The vapors passing through the mass of the catalyzer give rise to two kinds of products, one liquid, which may readily be condensed; the other gaseous, which may be collected in a gasometer.

The liquid products are subjected to distillation and

that fraction which boils up to 300 deg. F. to hydrogenation on nickel at 350 deg. F.

It results from the above that the catalytic decomposition of linseed oil on copper-magnesia, followed by a hydrogenation on nickel of the most volatile products, has the effect of yielding aromatic hydrocarbons. There is a cyclization of the fatty chain, and as the cyclic products thus obtained are free from sulphur, it has been possible to obtain cyclohexane and its derivatives.

It will be seen that this catalytic process permits of obtaining from a vegetable oil, a mixture of gasoline and kerosene which may be used as a motor fuel. The gasoline has a specific gravity of 0.7607 and the kerosene of 0.8644. Both are soluble in alcohol in all proportions.

THE Aerodynamic Section, Bureau of Standards, is constructing a new wind tunnel 10 ft. in diameter. The design for the tunnel is finished and the material for its construction is being rapidly assembled. The completion of this tunnel will give the Bureau exceptional facilities for all sorts of research work involving the study of the behavior of objects in a windstream.

# Elementary Principles of Exporting Are Important

Proper shipping and packing and absolute accuracy in making out drafts and shipping lists may appear to be somewhat minor details in the export trade but they are highly important in the end. Increasing demand for American cars abroad opens an encouraging market for automotive manufacturers. This article was prepared by an experienced exporter.

**A** MERICAN manufacturers produce something over 25 per cent more goods than can be consumed within the boundaries of the country. Production is by no means at its peak and there are many countries that are ready to receive more American goods. This is especially true of American automobiles. Manufacturers, especially those who are comparatively new in exporting, sometimes regard the exporting end of their business as something mysterious; something beyond their ken. It is true that many manufacturers have lost money by attempting to export their goods, but in many cases this has been due to a lack of knowledge of the fundamental principles of exporting.

Fluctuations of foreign exchange, of course, have played an important part in keeping the danger signal before the manufacturer who sometimes feels that he might be able to sell some of his goods in foreign countries. But that is a situation that will be but temporary. It will not be righted in a day, but eventually it will be righted. When that obstacle is removed as it already has been to some countries, the American manufacturer should be ready to step into the foreign markets, and, proceeding along sound business lines, successfully compete with the manufacturers of any other country in the world.

## Basic Points Essential

There are certain basic elementary principles of exporting. These are known to most manufacturers who have shipped their goods directly from their factories to foreign ports, but there are many who have not yet entered this field. Then, too, there are many who have entrusted this work to agents. Extreme caution should be exercised in choosing the man to handle goods at the port of embarkation.

A man who has spent considerable time as a salesman in South America, declared recently that if more manufacturers realized they could forward an article for overseas shipment almost as easily as they can for domestic shipment there would be many more engaged in the export business than there are. While the things he regards as extremely important points may seem of a somewhat elementary nature, especially to the manufacturer who has been engaged in the export business, they are, nevertheless, things the manufacturer should know. A good many people have told of the race characteristics of the Latin-American and other nationalities, and have discussed the psychology of selling in various countries, but most of these writers have taken it for granted that the manufacturer would know what to do with his order after it was obtained. That is where many American manufacturers have failed.

A good salesman will always send forward with his order minute shipping directions, stating the number of copies of the invoice and packing list that are to go out with the draft. These requirements vary in different custom houses. Naturally these instructions should be adhered to.

**The American salesman can usually sell goods in foreign countries, at least once, but if his employer, the manufacturer, does not meet specifications, does not ship his goods properly or makes errors in making out drafts or other papers, the manufacturer has no right to expect that salesman to send in repeaters.**

One of the chief difficulties confronting the shipping departments in the past seems to have been making the contents of the shipping case conform to the packing list. On the surface this appears to be a very minor sort of thing that might happen to anyone whose employees became a bit careless. But it is important. If the contents of the shipping case do not correspond to the items listed the consignee is subject to a fine. Then, too, these exported goods are not being shipped to within telephoning distance, and if shortages occur the buyer is at the mercy of the seller, for the draft is always for the entire amount.

The packing of goods is important in itself. Boxes should be bound with steel strips and, if possible, sealed, for the curse of the foreign buyer is pilferage. Each case should be numbered and the numbers should correspond to those on the packing list. In most South American countries, except in the British possessions, it is necessary to mark on these cases, in kilos, the weight of the case, the gross weight, net weight and the tare. The cubical contents must also be marked. This completes the packing operations at the factory.

## Making the Draft

Then there are the operations in the office. It has been said that 50 per cent of all manufacturers in the United States are unable to understand the difference between a sight draft and a date draft and this confusion has been known to result in rejection of shipments. If goods are sold on terms of 60 days, it is usually understood to mean that the buyer must pay for the shipment 60 days after he accepts the draft. But many drafts are made payable sixty days after the date made out, and no matter how long it may take for the draft to reach the consignee, it is due and payable 60 days after it has been made out at the factory in the country. It should also be remembered in making drafts that the manufacturer must compute the interest covering the

time the draft is out and add the interest charges into the total amount, as overseas firms will not pay interest charges on drafts unless such charges are specified in the order.

All manufacturers' drafts should be attached to packing lists and invoices and can either be sent to the forwarder of the goods, to be attached to the shipping documents, which include consular invoices, ocean steamship bill of lading and insurance certificates. Or they can be sent to the correspondent bank to be held and attached to the shipping documents upon their arrival.

Manufacturers can make arrangements with steamship agents, express companies, or railroad agents to pick up their shipments and forward them, all charges collect, at the port of destination. The shipper can also make arrangements at his bank to discount his draft. In this case he must present to the bank the draft with the invoice, packing list and the railroad bill of lading. A representative of the forwarding agent then gives the bank a trust receipt, covering the value of the documents, and here the manufacturer's identity with the shipment ends, save for the fact that he is liable to his bank for the amount of the discounted draft until such time as the consignee pays the draft and the money is returned to the bank.

In making bills of lading they should be marked, "For Export." This marking entitles the shipments to free storage at the port of embarkation for a reasonable period and eliminates the possibility of the forwarding

agent including in his charges money expended for putting the goods in storage.

Manufacturers should demand from their forwarding agents duplicate copies of the ocean bills of lading, insurance certificates and all forwarding charges.

It is a good plan, in fact almost a necessary one if the order is big enough, to cable the consignee immediately the shipment is cleared, giving him the name of the ship the consignment has gone forward on and the date of departure. If the order is not large enough to warrant cabling then the information should be sent by letter, and enclosed should be a copy of the packing list and invoice. These should be marked "duplicates," and in case the originals are lost the duplicates will be available. These duplicates should be sent by mail even if a cable is sent.

All this information is not intended to be construed as an article on "Exporting Made Easy," for it is not easy. There are many things to be watched, but if they are watched carefully a great deal of trouble can be eliminated. The principles set forth, it is true, are elementary, but in many cases failure to observe these principles have resulted in lost customers. Exporting requires close study and thorough investigation. The reliable salesman in the field is usually pretty well acquainted with the necessary steps to be taken in shipping goods to his particular territory, and the manufacturer would do well to abide by the suggestions the salesman offers.

## Belflex Fabric Spring Shackle

IT is well known that the wear of spring shackle bolts is one of the main causes of cars becoming noisy in operation prematurely, and to eliminate this trouble, improvements in the lubrication of shackle bolts have been made by many designers in recent years. Another method of eliminating this trouble has been adopted recently by several designers, which consists in completely eliminating the familiar spring shackle. The first step in this direction apparently consisted in providing the spring master leaf with a scroll at the end and securing this scroll to the spring hanger, but this method has not achieved any great success, probably owing to weakness due to concentration of strains at the point of attachment. The latest designs for pivotless shackles make use of fabric, and one of them is the Belflex, which is illustrated herewith.

It is claimed for this shackle, which is manufactured by the Belflex Corp., that it requires no lubrication and cannot rattle or squeak; that it will outwear the average spring shackle and that it also performs to a certain extent the functions of a shock absorber.

The tension type of Belflex shackle, which is the one here illustrated, is made by clamping together four or more strips of rubberized fabric, which thus form a link or shackle which is bolted fast to the spring at one end and to the frame bracket at the other. The required clamping pressure is obtained when the shackle is assembled on the car, when the nuts which hold the shackle to the spring and to the bracket are tightened up. The clamping faces of the top and bottom boxes protrude at an angle in such a manner that under rebound the fabric strips act as cushion between them, it is claimed. There is an appreciable difference in the

face angles of the two boxes, which is made necessary by the fact that the lower box is at all times rigid, while the upper one moves with the spring.

Thin corrugated separators are inserted between the fabric strips; they supply the required clamping surface and help to transfer the load from the clamping bolts to the cover and load plate. The fabric strips are composed of three plies of 37½ oz. duck, which has been given a skim coat of rubber. The top leaf of the spring is prepared for use with the shackle by punching holes for the bolts in it near the end and then turning the end up to the proper angle for setting the shackle link. The frame brackets are designed to give the link a vertical position under full load.

Endurance tests with these shackles were made at the mechanical laboratory of Cooper Union, New York, and gave results which are said to warrant the claims as to life reproduced earlier in this article.

Belflex spring shackle

# Advances in Power Presses and Dies Due to Automobiles

Demand of automotive industry has caused stage of perfection in forming and stamping operations that was hitherto unthought of. The ability of press and die manufacturers to successfully control the flow of cold sheet metal into certain shapes has aided economic production of cars.

By Henry J. Hinde\*

**T**HE art of producing sheet-metal stampings from a flat sheet while cold has made marked progress in recent years, and many articles are now made of sheet metal which were formerly produced by casting or forging, or in a lathe, milling machine, drill press or at the bench.

Forming and stamping operations especially have in many classes of work become very complex, and the art of drawing sheet metals, stimulated by the enormous demand of the automobile industry in particular, calling for most intricate shapes, has reached a state of perfection hardly imagined possible a few years ago. The results achieved by the ingenuity of the present-day press and die designers, and to no small degree also by the metallurgist, who comes into consideration through his improvements of the physical qualities of the metals used, are indeed revelations in economy of production, strength of stamped articles and the absolute interchangeability and beauty of appearance of the finished products.

## Development Due to Automotive Industry

The development of power presses, together with that of dies and special tools, has been so marked in the last twelve years, principally because of the demand for intricate stampings for the automobile trade, that it is believed a far greater advance has been made than at any other period in the history of the business. This development has not wholly been confined to the working of sheet metal, for, as previously stated, the demand for accurate duplication of parts and the great quantities in which they are desired has resulted in power presses being used for sizing forged steel parts which were formerly finished by means of saddle milling and similar operations. It has been found that manufacturers can produce greater quantities with much greater accuracy and with such a reduction in machine shop production expense by the use of what is known as knuckle-joint or cold-swaging presses in sizing the finished working surfaces on these forgings, that a number of equipments have been installed for work on steering knuckles, brake levers, connecting rods and other similar forgings and castings. These presses are built in sizes capable of exerting a pressure up to 2000 tons and over, and it is claimed that size limits of 0.001 in. can be successfully maintained in operations of this character.

Although this marked advance is due to the automobile industry more than to any other one factor in re-

cent years, at the same time the economical production of motor cars was made possible solely on account of the ability of the press and die manufacturers to successfully control the flow of the cold sheet metal into certain forms and shapes, by means of properly constructed dies and presses of such power and design that wonderful results have been obtained. As an illustration of this a wire-wheel hub is shown in Fig. 1.

This hub requires a blank 16½ in. diameter and 5/32 in. thick. Attention is called in particular to the numerous niches or pockets successfully formed into the circular shape, and also to the fact that the stamping was first drawn to a considerable depth at the narrow neck. The end of the neck or bottom of the stamping was then removed and this metal was made to flow back and expand to a considerable degree beyond its former small diameter without even stretching or thinning the metal in the reforming operations, thus proving conclusively how successfully the metal was controlled and forced to flow back into its larger diameter with an opening in the bottom much smaller than the former small diameter of the neck of the stamping.

In the production of brake drums, front and rear hubs and spoke flanges the conditions that have to be fulfilled by the dies are that the product shall be absolutely interchangeable; that no machine work shall be performed upon the stampings when coming from the press, excepting some reaming and thread cutting, and that the strength of the material shall remain unimpaired. In addition it is imperative that all cylindrical parts be smooth and true and of standard diameter, allowing less than the commercial tolerance of variation. The work involves a most careful planning of the interrelation of the several operations, so that at no time the material shall be overstrained or reduced in thickness, and that the dies shall not be subjected to excessive wear in order to maintain uniformity of size.

## A Straight-Column Press

A straight-column press has been developed especially for such work by the Toledo Machine & Tool Co. which is of unusually rugged proportions and weighs about 145,000 lb. It is double-gearred with a ratio of 40:1 and fitted with a very powerful friction clutch in combination with an effective brake and hand-lever control, so that the machine may be started or stopped at any part of the stroke of the slide up or down. The frame consists of four pieces—the bed, the two uprights and the crown—which are held together by four massive tie rods passing through the said crown, uprights and bed. When the frame is assembled these tie rods are

\*President and General Manager of The Toledo Machine & Tool Co. From a paper presented before the American Society of Mechanical Engineers.

heated. The nuts are then screwed home and the rods permitted to cool. In this manner, through the tendency of the rods to shrink, an enormous pressure is exerted by the rods upon the frame that renders the entire structure practically an integral one and brings all the working stress upon the tie rods.

Axle housings are made of steel plate up to  $5/32$  in. in thickness, and the requirements are that the stampings be perfectly straight and flat so that when the two halves of a housing are joined together by welding they form a perfect casing without warp. A powerful double-crank press developed for this purpose weighs about 95,000 lb. and is capable of forming and stamping cold at one blow axle-housing halves about 40 in. in length of steel plate up to  $5/32$  in. in thickness, the blank having been cut previously to proper shape.

One modern form of toggle drawing and deep-stamping press, such as is used for making engine pans, radiators and other similar articles of the comparatively lighter gages of metal, has two slides, an outer slide for clamping the blank and holding it while the work is being drawn, and an inner slide for doing the drawing, stamping and forming operation. Presses of this character are also made in the double-crank type with a considerable distance between the uprights and weighing as much as 600,000 lb. Such presses are used for body forming, for making cowls, dashes, fenders, etc.

#### Special Designs

The forming of channels and side rails for automobile frames and similar requirements has resulted in the designing and building of special presses particularly adapted for this work. The side rails, for instance, are preferably first blanked in a double-crank press as much as 218 in. between the uprights. The largest sizes of these presses weigh in the neighborhood of 500,000 lb.

The forming operations are performed in a specially designed press, the outstanding feature of which is that

the operation is diametrically opposite that of the ordinary toggle drawing or deep-stamping double-action presses. The channel-forming press has a movement entirely mechanical that brings the tools down and at rest on a flat blank, or sheet, by means of a toggle motion, and in this position the machine is capable of a resistance pressure upward of 2000 tons. While this first toggle movement is at rest, another movement is brought into play, forming up the sides of the channel or frame. The machine in its operation completes the one cycle when the stamping lies on the face of the dies completely formed, with the result that the web, or bottom of the stamping, remains as flat as it was in the original sheet. In other words, the bottom or web of the channel is held perfectly flat during the operation. Several of these presses have been built and are in most successful operation. They weigh upward of 600,000 lb. each. One of these presses with five men will do the work of three hydraulic presses with fifteen men, to say nothing of the large force required to straighten the rails when hydraulic presses are used.

Still another interesting feature that the automobile trade has developed is the smoothing-out process for certain of its stampings, more particularly the tapered, stamped-steel radiator front or casing. Because of its slightly tapering form it was found difficult to produce a stamping for this piece so free from waves, or buckles, that it would show smooth over the finally enameled and varnished surface. The requirements were successfully met by developing a set of tools to receive the finished stamping and allow an exceedingly small space for water to flow just inside of the stamping around the steel form supporting the stamping. It was necessary to exert a pressure of some 2000 tons on the outer surface of the stamping to prevent seepage or leaking, and to supply water to the die through a  $3/4$ -in. pipe by means of an accumulator with sufficient force to smooth and iron out the unevenness and waves in the original stamping.

## Keeping a Rubber Factory Clean.

**F**ACTORY cleanliness under the direction of a Sanitary Department was described in an address delivered by William Jameson, advisory engineer of the Fisk Rubber Company, before the National Safety Council at Boston recently. Mr. Jameson said that in one rubber factory a sanitary department was organized about two years ago under the supervision of a man who had no other duties than to keep the plant clean. A considerable amount of discussion and many conferences were held before any attempt was made to get under way. A few of the sweepers who were then under the supervision of production foremen were taken over; a week or so later another group was transferred to the sanitary department, and so on, until the entire group of sweepers had been transferred.

Immediately better results were obtained at a considerable reduction in cost. Some difficulty was encountered at first in defining the duties of the sanitary department in view of the fact that these men had been called upon to carry on so many different activities under the old plan. This condition was easily adjusted and in some cases it was necessary for the foremen to hire a helper to do the work the sweeper had been doing. In the plan in operation at this factory one superintendent exercises general supervision over the entire department assisted by two foremen—one for days and one for nights.

Three squad leaders of recognized ability—two on the day force and one on nights, perform emergency work and work with and check men when in squads or on special work.

During the day, in departments or locations where litter accumulates in great quantities, one or more sweepers are assigned and put in all their time in one locality. For the most part the sweeping is done by placing men in two squads, each squad looking after certain sections of buildings, covering all sections at least once daily.

The night sweepers work in one squad and usually start at the top floors and work to the basement, returning in the early morning to clean those places where the plant has been operated at any time during the night.

The entire day force and many of the night force work Saturday afternoons and make a general weekly cleaning, as most of the machinery is idle then and the sweepers have the opportunity of doing a thorough job.

In addition to maintaining plant sanitation, the sanitary department is also held responsible for provision of adequate toilet and washing facilities, in compliance with state rules and regulations. Moving of departments from one location to another, the changing from male to female help, etc., requires considerable vigilance to keep the matter within the law.

## Cause of Skidding at Turns

Editor, AUTOMOTIVE INDUSTRIES:

I have never been able to comprehend what seemed to me an adequate cause for the skidding of an automobile. The following considerations may be valid; I have never seen them in print.

In rounding a curve, the front wheels get into the straight-away while the rear wheels are on the curve. In addition to the deceleration of the rear wheels as they approach the straight-away there must be an inertia effect due to the fact that the inside and outside wheels are moving at different speeds while on the curve and at the same speed when they have entered the straight-away. I do not know how quickly this change takes place, but it would seem to be but a very short time.

Referring to the accompanying sketch, assuming arbitrary and perhaps impossible data for the purpose of illustration, suppose the inner wheel to be turning in a 10 ft. radius and the outer wheel in a 15 ft. radius. Then the inner wheel might be moving 12 ft. per sec. and the outer wheel 18 ft. per sec. at the position A.

Suppose we take 100 lb. as concentrated at each wheel.

The outer wheel would have  $\frac{(18)^2 \cdot 100}{64}$  foot-pounds of energy stored in it and the inner wheel  $\frac{(12)^2 \cdot 100}{64}$  foot-pounds of energy.

If on the straight-away they are both going at the rate of 15 ft. per sec., the outer wheel would have lost about

$$\frac{(18)^2 \cdot 100}{64} - \frac{(15)^2 \cdot 100}{64} = 211 \text{ foot-pounds of energy and}$$

the inner wheel would have gained about  $\frac{(15)^2 \cdot 100}{64}$

$$- \frac{(12)^2 \cdot 100}{64} = 126 \text{ foot-pounds of energy.}$$

If this change took place in one-tenth of a second it would have caused a pressure of 2110 lb. on the outer wheel and a pull of about 1260 lb. on the inner wheel.

This might have a bearing on the spring suspension also.

These effects remind one of an athlete using a pair of dumb-bells to extend his jump.

E. J. STODDARD.

We doubt very much whether there is any particular tendency for a car to skid at the instant the driver straightens out the front wheels. In fact, this motion is the same as that which is commonly used to correct a skid.

Our explanation of a skid on a curve is as follows: The centrifugal force on a car while going around a curve tends to cause the whole car to leave its circular path radially. This tendency is resisted by the adhesion of the wheels to the road. The centrifugal force acts at the center of gravity and may be divided into two components, along the front and rear axle axes, which are the center lines of the two resisting forces. These components will be proportional to the weights on the front and rear axles, respectively. If the resisting forces (resistance to lateral skidding) were also proportional to the weights on the

respective axles, as they might be supposed to be, the front and rear wheels would begin to skid at the same time and there would be a sideways sliding of the whole car, instead of the slowing action which actually takes place. But owing to the driving force on the rear wheels the adherence of these wheels to the ground is probably much less than that of the non-driving front wheels. The result is that the centrifugal force and the lateral resisting forces are no longer in balance and the car slides more easily at the rear than at the front. Therefore, when the centrifugal force becomes great enough, skidding begins.—Editor.

## Low Unsprung Weight Axles and Spring Action

Editor, AUTOMOTIVE INDUSTRIES:

The universal joints in the DeDion type of drive are subject to the propeller shaft torque times the reduction rate divided by two, because of the balance gear. In such an example as was cited in your editorial of Nov. 3, the torque at the universal joints would be twice that of the propeller shaft, but at one-fourth the number of revolutions. Hence joints made sufficiently stiff to stand the torque would be very durable. The short rigid Cardan shafts running at low revolutions reduce to very small values the radial stresses due to unbalance or whip. The universal joints of the DeDion drive system are by no means as severely loaded as would appear from casual inspection.

It seems that the up and down motion of the wheel in the Rumpier system would vary the angular velocity of the drive to an unusual degree, and that it would be necessary to introduce an elastic member, such as a long propeller shaft, between the engine and differential to absorb this variation.

The Cowey suspension is very interesting. The writer at one time felt that the "sympathetic" action shown should be included in the cross spring design, but was discouraged by the complication involved. This seems to have been worked into one of the late cross spring constructions.

At one time a trial was made by securing two front half elliptic springs to a front axle in the usual manner, and then the eyes of the opposite springs were connected by long rods, threaded so that tension could be applied, draw-

ing the spring ends toward one another; thus twisting the spring slightly. This reproduced conditions where the springs were twisted, either by improper installation, or by centrifugal force, or by one wheel rising more than the other. The axle was inverted, with the springs resting on the floor, and a lever was used to press down the axle, thus flexing the springs. The spring action was found to be very erratic—a sort of flip flap—snappy motion, such as would be felt when pressing the bottom of a pan inward and outward. Take a flexible piece of steel, like a spring rule, and attempt to twist and bend it at the same time, and the peculiar action will be realized. Some such action may be accountable for the peculiarities exhibited by suspensions—for instance, the excessive stiffness recorded in the seismograph tests made by Dr. Liebowitz.

JOSEPH W. RIDGWAY.

## Uniformity in Fuel Quality

Editor, AUTOMOTIVE INDUSTRIES:

The recent editorial in AUTOMOTIVE INDUSTRIES regarding the necessity of Improving the Fuel as well as the Engine is very much to the point. It is quite possible to-day to build engines that can operate on almost any

liquid that will support combustion, but only along certain narrow lines would there be a chance of their being commercially successful. The great automotive industry and the equally great industry of supplying the required fuel were both built up on the foundation of a source of power of extreme simplicity embodied in the now more or less conventional gasoline engine. In spite of the education of the public in handling things mechanical any great departure from this simplicity will be a serious handicap to both industries.

I do not believe that we will have to fear any such result if the oil industry will really try to produce a fuel that can be handled satisfactorily in engines of simple form. The general characteristics of such a fuel are being better understood every day.

In closing I want to say a word regarding uniformity in the quality of fuel. Without a reasonable degree of uniformity we cannot expect to get any really economical operation. The automotive engine to be satisfactory must be to a large extent automatic in its operation. Wide variations in fuel characteristics in viscosity and evaporation temperatures will inevitably lead to waste because of the impossibility of correct metering or the proper application of heat.

HENRY M. CRANE.

## The Market in British Soudan

THE report on Anglo-Egyptian Soudan for 1920, written by Maj.-Gen. Lee Stack, the Governor-General, has just been issued by the British Department of Overseas Trade. The country continues to prosper, but ever-recurring throughout the report is the cry that lack of transport is holding the Soudan back. Difficulties of transport retarded trade with Abyssinia, held up lumber operations, rendered it impossible to transfer grain to famine areas, kept the produce of Darfur, Mongalla, and Nuba Mountains rotting in these provinces, forced Kas-sala cotton to rely on an insufficiency of camels, and restricted vaccination when a fearful epidemic of small-pox broke out in the Upper Nile.

The Soudan Government expects to have a \$4,000,000 budget surplus this year. This would be well spent in improving transport facilities. Work along this line has already started, however. Stone quarries and cement factories are being worked, forest and other roads are being built, wells are being bored so as to make arid areas accessible, and Khartoum (whose roads are considered too wide!) is being laid out afresh. A motor transport service has been instituted between Tonga and Talodi, while a fleet of surplus army trucks has substituted worn out cars on the Rejaf-Abu (Belgian Congo) road. Freight rates high on this route because gasoline is expensive and rubber tires cannot last on the rough roads. It is thought that iron-tired steam wagons will ultimately take the place of these trucks. Five applications were made to the Government for mechanical transport concessions last year. As it is not prepared to grant route monopolies to private concerns, however, no further action has yet been taken by the applicants.

The Soudan imports practically all its fuel. Both the Shell and Anglo-Persian groups are at present negotiating with the Government for the right to prospect for oil in the Red Sea littoral. Since oil has been struck in adjacent coastal regions there seems a chance that borings should prove successful. The Soudan Development Co., using charcoal-burning tractors in the country, is experimenting in growing wood of rapid growth for the purpose of maintaining fuel supply. The experiment, if successful, is regarded as being of importance.

As matters stand, the Soudan does not appear to be an attractive field for exporters looking for immediate sales, but the country has, without doubt, a big future, and an agency at Port Soudan or Khartoum should ultimately prove remunerative.

## Official Report on R-38 Disaster

THE official report of a court of inquiry appointed to look into the disaster to the R-38 throws some further light on that tragedy. It is brought out that the airship, having completed some 30 hours' trial, including 15 minutes at full speed—60 knots—was flying at a height of about 1200 ft. She was carrying out rudder and elevator tests at a speed of 45 to 50 knots. Almost extreme helm with a quick reversal was being used, which brought a heavy force on the after portion of the hull, due to the swing of the stern.

During this maneuver the structure failed between frames 9 and 10, the first indication of which to ground observation was a slackness of the fabric at this particular point.

The ship then broke into two portions. The forward portion caught fire at the fracture, at the moment of or shortly after separation. The fire probably originated in a spark from the electric leads, which became fractured at a point in the immediate vicinity of a similar fracture in the fuel mains. As all sources of electrical energy were situated in the forward portion only, the rear portion was not affected, as electric leads in the latter portion became dead immediately the fracture took place.

The fire in the forward portion spread rapidly, due to the presence of escaping gasoline in the keel. An explosion followed, which led to the collapse of the structure and the ignition of the liberated hydrogen gas.

A second explosion took place when the forward portion reached the water. Meanwhile the after portion descended comparatively slowly, but did not catch fire. Four of the five survivors were in this portion and were rescued uninjured.

# Marketing Costs and Their Tendency to Increase

Production economies are not likely to be secured rapidly enough to offset higher cost of distribution. The costs, therefore, must be reduced by a more efficient method of marketing. Increasing competition demands lower prices and to meet this demand all avoidable waste must be eliminated.

By Harry Tipper

**A**N examination of commodity prices extending over a period of the last century indicates that there were two periods of rise and fall, or what is termed "the long swing cycle of prices" in this century of consideration.

The low point reached between the War of 1812 and the Civil War is considerably higher than the low point reached about 1897, while the peak reached during the Civil War is not so high as the peak reached after the World War in 1920.

If a similar curve of commodity prices be taken from Great Britain from the Napoleonic War to the World War, this curve will show a general decline in prices up to 1896. The Crimean War and the Boer War did not disturb the economic fabric of Great Britain sufficiently to introduce a full peak.

At the close of the Napoleonic War from 70 to 80 per cent of the wholesale price of the commodity was involved in the materials, labor and capital required to produce the commodity.

In 1896 from 40 to 50 per cent of the wholesale price was required to furnish the labor, and raw materials and capital

for production. In this period of declining prices the percentage of the sales price involved in the distribution and marketing grew larger, while the percentage of sales price involved in manufacturing the products became smaller.

During the period of rising prices since 1896 the percentage of the sales price involved in the work of distribution and marketing has increased still further, so that there has been no change in this tendency.

An examination of these statistics indicates very fully that the concentration of manufacturing in larger units has been accompanied by a constant increase in the cost of distribution and marketing from those points.

Up to about the year 1900 the increase in the cost of distribution and marketing was more than absorbed by the increased economies effected in production and manufacturing, so that the sales prices could be reduced. Eliminating the peak produced by the Civil War, there is constant diminution in the sales price for nearly a century, due to the growth of machinery and machine methods, improved equipment of manufacturing and pro-

duction and the possibility of increasing the productivity of labor by these means. Improvements were made in the methods of distribution by the extension of the newer systems of transportation and their development, but these improvements were not sufficient to offset the constantly increasing requirements of distribution and marketing and the increasing proportion of the total cost entering into those elements of business.

Reading from the past history there is no indication that the cost of distribution and marketing will decrease. In fact, the costs have had a tendency to rise more sharply during the last twenty years and this would indicate the

general tendency of distribution and marketing to absorb a larger percentage of the sales price as the area of marketing increases and the intensity of competition becomes more severe.

In common with other lines of industry, the automotive manufacturer faces the probability of increase in the costs of marketing and distribution due partly to the increased difficulty in finding a market and partly to the intensity of competition for every portion of the market. It is not probable that the production econo-

mies can be secured at a sufficiently rapid rate to offset the increased cost of marketing and distribution, and consequently the elements of marketing must be analyzed more carefully in order that the wastes may be eliminated and the costs kept down by a greater efficiency in the methods. Even with bulk material, the price paid by the user of the material is usually double the cost required to produce the material and in the case of commodities passing through a number of different hands, when they arrive at the user, the final price is frequently 500 to 600 per cent more than the original production cost.

A considerable part of this cost comes under the head of avoidable wastes.

The organization of any establishment in business is in the best economic position when its marketing efforts are limited to the least amount of territory or area required by the character of the consumption and the intensity of the competition for that commodity. One of the largest elements in the avoidable wastes of marketing has been the tendency to the extensive cultivation of markets, because of our ignorance of the laws governing the cost of

---

**T**HE growth of the automotive industry in the past has been rapid because there was a heavy demand for a product that superseded less efficient methods. That demand has been met to a great extent and the future growth of the industry will be in proportion to the general growth of the country from a standpoint of population, wealth and business activity. The old marketing methods that were justified because of the abnormal demands upon the manufacturer, must be discarded and more scientific and efficient ones installed.

---

marketing and our ability to sell irrespective of that cost so long as the manufacturing capacity was not much more than the market requirements demanded.

Since the Civil War, during the years of declining prices following that period, the economies in manufacturing came with such rapidity that the wastes in marketing were easily absorbed unnoticed and the prices could be reduced without respect to the marketing wastes.

During the era of rising prices the manufacturing capacity of the United States was not larger than was required to meet the possibilities of the domestic market, and, as a consequence, there was not sufficient competition for the markets to require the reduction of price regardless of cost.

With the surplus manufacturing capacity possessed by the United States at present, the competition for the market will demand the reduction of the sales price to the lowest possible denominator and this cannot be done profitably without a re-examination of the marketing methods and an entirely new study of the economic basis upon which they should be considered.

It is common knowledge that in a large business, dealing with large volumes of material, in accordance with the law of diminishing returns the cost of getting a unit of sale increases as the volume grows, but no attention has been paid to the economic limit beyond which it is not profitable to increase the volume of sales on the present basis of efficiency.

Manufacturing establishments have been increased, because of the supposed possibilities of an increased market. While the increase in manufacturing has been justified during the era of rising prices, to secure a volume sufficiently large to take up this manufacturing capacity under present conditions may eliminate the possibility of profit, unless the proportionate cost of the market can be decreased by the introduction of better methods and the elimination of the present wasteful elements in the attempt to secure the orders.

In the automotive business particularly, the rapid absorption of these units of transportation into the economic fabric has built up a manufacturing capacity and a price condition, including an enormous number of inefficiencies and wastes extending all through the manufacturing end and becoming very obvious in the methods of marketing adopted. Because of the demand created by the necessity of absorbing this unit of transportation in adequate quantities, the price had no special relation to the cost and it did not suffer from any great intensity of marketing competition.

The automotive business is now approaching the period when having taken its place as an integral part of the social and business fabric, its growth will depend more exactly upon the growth of the whole fabric. In other words, its progress will be limited more definitely to the general progress.

Up to the present the business has grown much faster than the total population or the total wealth of the country, because it superseded less efficient methods and required this growth after it had proved its value. That adjustment is about over, and its future growth will be only in proportion to the general growth from a standpoint of population, wealth and business activity.

In the course of this rapid growth, speed of production and large contact with the market were the important elements of the problem to be met. Under such circumstances wastes of all kinds crept into the business end. With the large potential market in front of the automotive manufacturer, wide, extensive marketing methods carried with little relation to their efficiency were perhaps more suited to the conditions.

These conditions have changed and the marketing methods justified because of these conditions must be thrown to one side and newer methods adopted, more analytically determined and with strict knowledge of the manufacturing establishment, in proportion of its production in relation to the total market possibilities.

## Peruvian Business Situation

It is difficult to determine the number of automobiles in Peru. Returns from the provinces are slow in coming in, and in some cases do not arrive at all. For Lima the municipal authorities give the following figures:

Automobiles for public hire.....	629
Private automobiles .....	1300
Trucks .....	300
	2229

Assuming there are half as many automobiles and trucks outside Lima as in it, we have.....1114

Total number of automobiles and trucks in Peru...3343

There are, however, probably more than this. From 1909 to 1920 there were exported from the United States to Peru 4836 automobiles and trucks. Enough more cars and trucks have been exported from the United States to Peru during 1921 to raise the number to 5000. Allowing that 25 per cent have been worn out, or destroyed by misuse, this leaves 3750. But no account has been taken of automobiles that came from Europe to Peru during the past ten years, some of which are to be seen in Lima.

The Peruvian import statistics for automobiles at first gave only the value; then weight and value; and beginning with 1917, weight, value and number, for automo-

biles, but only weight and value for trucks. In the subdivisions for weight and value the countries are indicated from which the goods came, but for number only the total is given without reference to country of origin. No figures are yet available for 1920. For the three years for which data are available Peruvian statistics show that the importations of automobiles alone, trucks not included, amount to 1798. Taking into account the number of automobiles and trucks that have come to Peru from Europe, it may not be erroneous to assume that there are 4000 automobiles in Peru, either running or that may easily be put in running condition if the owner desires.

There are probably 1000 tractors in Peru. Almost all leading North American makes are represented, and many European. A light tractor of 20 hp. and three plows seems to be the favorite. As Peru is a land of large farms, plantations or ranches, it would seem to lend itself well to the exploitation of the power idea in farming, and furnish an excellent territory for future tractor business.

Almost all leading makes of North American automobiles are in use in Peru, from the light car to the limousine, it being surprising how many high grade cars are to be found in the republic. Records of the municipality show that not more than 10 per cent of the cars and trucks in Lima are of European make.

## Is a Fuel Stringency Near?

MOTOR fuel has recently been cheap; hence the need for economizing in its use has not been appreciated. There have, however, been recent marked increases in the price of crude oil and this has already been reflected in an increase in the price of gasoline. The fact that this has occurred at a time of year when the price of this commodity usually undergoes a seasonal decline is significant and the reason is not far to seek.

For several years our domestic consumption of petroleum has exceeded the domestic production. The widening gap has been filled largely by imports from Mexico. The Mexican fields, which have been phenomenal producers, have, with one important exception, gone to salt water, and their potential production fallen off with great rapidity. During the first half of the current year nearly one-quarter of our petroleum supply came from Mexico. The supply from present Mexican fields is extremely uncertain. Obviously, then, the oil situation in the United

States is in a critical state. Mexican crude is not rich in gasoline, but it has had a vastly important effect upon the price of domestic crude, and it is this price which must, in the last analysis, control the price of motor fuel.

Even in this year of general business depression petroleum consumption has continued to increase. It will continue to increase until price changes interfere, but there is nothing to indicate that petroleum production can continue to increase in proportion to increased demand. It seems certain that we shall never be able to produce enough crude in this country to meet the domestic demand unless a great increase in price materially curtail consumption. With the Mexican oil supply rapidly failing there is good reason to expect a fuel stringency with swift advance in price.

It is idle to assume that newly discovered domestic oil fields will result in a sufficient production to keep pace with a steady increasing consumption, for such discoveries have failed to do so for many years past. More oil will be discovered in this country, but that the quantity thus made available can replace the failing supply of existing fields, much less keep pace with an ever increasing demand, is incredible.

The obvious deduction which the automotive industry must face, unpleasant though it may be, is that motor fuel is practically certain to advance rapidly in price in the not distant future. We do not say that there will be a serious shortage of fuel in the near future, but we do anticipate a stringency in the supply which will mean considerably higher prices and have a pronounced effect upon automotive sales.

It is easy to argue that fuel cost is not a large item in the operation of the average car or truck, but it certainly is in the case of vehicles at the lower end of the price scale. A vehicle which uses three gallons of fuel a day 300 days in the year will cost the owner, for this item alone, \$270 a year with fuel at 30 cents a gallon. For a car costing around or under \$500 this is indeed a serious item. Suppose, now, that fuel doubles in price. At the same rate of consumption it is easy to see that the annual fuel bill would nearly equal if not exceed the first cost of the car. That such a situation would materially increase sales resistance can scarcely be doubted.
